Comments and Replies

Notice to Contributors

The maximum length of an *ASR* paper is typically ten (10) printed pages or thirty (30) typed manuscript pages including space for tables, figures and references. Due to space limitations, we must request contributors to conform to this norm as closely as possible.

To permit anonymity in the review of manuscripts, keep identifying material out of the manuscript. Attach a cover page giving authorship, institutional affiliation and acknowledgments, and provide only the title as identification on the manuscript and abstract.

ASA Multiple Submissions Policy: Submission of a manuscript to a professional journal clearly implies commitment to publish in that journal. The competition for journal space requires a great deal of time and effort on the part of editorial readers whose main compensation for this service is the opportunity to read papers prior to publication and the gratification associated with discharge of professional obligation. For these reasons, the American Sociological Association regards submission of a manuscript to a professional journal while that paper is under review by another journal as unacceptable.

SUBMISSION AND PREPARATION OF MANUSCRIPTS

1. Submit four (4) copies and retain the original for your files. Copies may be Xerox, mimeograph or multilith, but not carbons.
2. Enclose a stamped self-addressed postcard for acknowledgment of manuscript receipt. *Manuscripts will not be returned.* Please do not send your original copy.
3. All copy must be typed, doublespaced (including indented material, footnotes and references) on 8½ by 11 inch white opaque paper. Lines must not exceed six (6) inches. Margins must be a minimum of one inch.
4. Include four (4) copies of an abstract of no more than 150 words.
5. Type each table on a separate page. Insert a location note at the appropriate place in the text, e.g., "Table 2 about here." Send copies, retain originals.
6. Figures must be drawn in India ink on white paper. Send copies, retain originals.
7. Clarify all symbols with notes in the margins of the manuscript. Circle these and all other explanatory notes not intended for printing.
8. Footnotes should not be placed in the body of the text. Type them (doublespaced) and attach them as a separate appendix to the text. Number them consecutively throughout the text. Footnotes are to be kept to a minimum and used only for substantive observations. Source citations are made within the text rather than in footnotes.
9. Acknowledgments, credits and grant numbers are placed on the title page with an asterisk.

REFERENCE FORMAT

- A. *In the text:* All source references are to be identified at the appropriate point in the text by the last name of the author, year of publication and pagination where needed. Identify subsequent citations of the same source in the same way as the first, not using "ibid.," "op.cit.," or "loc. cit." Examples follow:

1. If author's name is in the text, follow it with year in parentheses. ["... Duncan (1959) ..."]
2. If author's name is not in the text, insert, in parentheses, the last name and year, separated by a comma. ["... (cf. Gouldner, 1963) ..."]
3. Pagination (without "p." or "pp.") follows year of publication after a colon. ["... Kuhn (1970:71)."]
4. Give both last names for dual authors; for more than two use "et al." in the text. When two authors have the same last name, use identifying initials in the text. For institutional authorship, supply minimum identification from the beginning of the complete citation. ["... (U.S. Bureau of the Census, 1963:117) ..."]
5. Separate a series of references with semicolons and enclose them within a single pair of parentheses. ["... (Burgess, 1968; Marwell et al., 1971; Cohen, 1962) ..."]

- B. *In the appendix:* List all source citations by author, and within author by year of publication, in an appendix titled "References." The reference appendix must be complete and include all references in the text. The use of "et al." is not acceptable in the appendix; list the names of all authors. (See A. 4. for text format.)

If there is more than one reference to the same author and year, distinguish them by the letters, a, b, etc. added to the year. ["... Levy (1965a:331) ..."] Give the publisher's name in as brief a form as is fully intelligible. For example, John A. Wiley and Sons should be "Wiley."

If the cited material is unpublished, use "forthcoming" with name of journal or publisher; otherwise use "unpublished."

Use no underlining, italics or abbreviations.

Examples follow:

1. *Books:*
 - Jud, Gerald J., Edgar W. Mills, Jr. and Genevieve Walters Burch
1970 *Ex-Pastors*. Philadelphia: Pilgrim Press.
 - U.S. Bureau of the Census
1960 *Characteristics of Population*. Volume 1. Washington, D.C.: U.S. Government Printing Office.
 - Bernard, Claude
[1865] *An Introduction to the Study of Experimental Medicine*. Tr. Henry Copley Greene. New York: Dover.
2. *Periodicals:*
 - Conger, Rand
Forth- "The effects of positive feedback on direction and amount of verbal-
coming zation in a social setting." *Pacific Sociological Review*.

The maximum length of an *ASR* paper is typically ten (10) printed pages or thirty (30) typed manuscript pages including space for tables, figures and references. Due to space limitations, we must request contributors to conform to this norm as closely as possible.

To permit anonymity in the review of manuscripts, keep identifying material out of the manuscript. Attach a cover page giving authorship, institutional affiliation and acknowledgments, and provide only the title as identification on the manuscript and abstract.

ASA Multiple Submissions Policy: Submission of a manuscript to a professional journal clearly implies commitment to publish in that journal. The competition for journal space requires a great deal of time and effort on the part of editorial readers whose main compensation for this service is the opportunity to read papers prior to publication and the gratification associated with discharge of professional obligation. For these reasons, *the American Sociological Association regards submission of a manuscript to a professional journal while that paper is under review by another journal as unacceptable.*

SUBMISSION AND PREPARATION OF MANUSCRIPTS

1. Submit four (4) copies and retain the original for your files. Copies may be Xerox, mimeograph or multilith, but not carbons.
2. Enclose a stamped self-addressed postcard for acknowledgment of manuscript receipt. *Manuscripts will not be returned.* Please do not send your original copy.
3. All copy must be typed, doublespaced (including indented material, footnotes and references) on 8½ by 11 inch white opaque paper. Lines must not exceed six (6) inches. Margins must be a minimum of one inch.
4. Include four (4) copies of an abstract of no more than 150 words.
5. Type each table on a separate page. Insert a location note at the appropriate place in the text, e.g., "Table 2 about here." Send copies, retain originals.
6. Figures must be drawn in India ink on white paper. Send copies, retain originals.
7. Clarify all symbols with notes in the margins of the manuscript. Circle these and all other explanatory notes not intended for printing.
8. Footnotes should not be placed in the body of the text. Type them (doublespaced) and attach them as a separate appendix to the text. Number them consecutively throughout the text. Footnotes are to be kept to a minimum and used only for substantive observations. Source citations are made within the text rather than in footnotes.
9. Acknowledgments, credits and grant numbers are placed on the title page with an asterisk.

REFERENCE FORMAT

- A. *In the text:* All source references are to be identified at the appropriate point in the text by the last name of the author, year of publication and pagination where needed. Identify subsequent citations of the same source in the same way as the first, not using "*ibid.*," "*op.cit.*," or "*loc. cit.*" Examples follow:
1. If author's name is in the text, follow it with year in parentheses. [". . . Duncan (1959) . . ."]
 2. If author's name is not in the text, insert, in parentheses, the last name and year, separated by a comma. [". . . (cf. Gouldner, 1963) . . ."]
 3. Pagination (without "p." or "pp.") follows year of publication after a colon. [". . . Kuhn (1970:71)."]
 4. Give both last names for dual authors; for more than two use "et al." in the text. When two authors have the same last name, use identifying initials in the text. For institutional authorship, supply minimum identification from the beginning of the complete citation. [". . . (U.S. Bureau of the Census, 1963:117) . . ."]
 5. Separate a series of references with semicolons and enclose them within a single pair of parentheses. [". . . (Burgess, 1968; Marwell et al., 1971; Cohen, 1962) . . ."]
- B. *In the appendix:* List all source citations by author, and within author by year of publication, in an appendix titled "References." The reference appendix must be complete and include all references in the text. The use of "et al." is not acceptable in the appendix; list the names of all authors. (See A. 4. for text format.) If there is more than one reference to the same author and year, distinguish them by the letters, a, b, etc. added to the year. [". . . Levy (1965a:331) . . ."] Give the publisher's name in as brief a form as is fully intelligible. For example, John A. Wiley and Sons should be "Wiley." If the cited material is unpublished, use "forthcoming" with name of journal or publisher; otherwise use "unpublished."

Use no underlining, italics or abbreviations.
Examples follow:

SEX AND THEORIES OF DEVIANCE: TOWARD A FUNCTIONAL THEORY OF DEVIANT TYPE-SCRIPTS *

301-05
Am 35

ANTHONY R. HARRIS

University of Massachusetts, Amherst

American Sociological Review 1977, Vol. 42 (February):3-16

Given available evidence on official and hidden criminality, conceptual neglect of the sex variable, not simply of women, is seen as having dire consequences for most contemporary criminal deviance paradigms and, consequently, as providing the major failure of deviance theorizing in this century. The outlines of a new paradigm are introduced, "the functional theory of deviant type-scripts," which suggest that everyday expectancies for deviance—which link types of actors to types of roles and which serve dominant social interests—at once account for our professional failure to include the sex variable in theories of criminal deviance and, more importantly, provide the single strongest theoretical account of the very striking cross-cultural difference in male and female criminality.

INTRODUCTION

The failure to study noncriminals proved a disaster to early work on criminal deviance. Putatively, the failure was a methodological one; in looking for a relationship between cranial shape and criminal propensity, phrenologists looked only at prisoners, thereby begging the question of how this purported relationship was distributed in the population at large (cf. Vold, 1958). The phrenologists' error, however, was almost certainly an artifact of a more fundamental conceptual blindness—the inability to imagine that rates of the "lower propensities" might be higher in the noncriminal population at large than among prisoners. Curiously, modern deviance theorists have applied the lessons learned from this sort of mistake only selectively. As a consequence, the general power of contemporary criminal deviance theory is only marginally greater than it was in the phrenologists' day. I am referring to a critical weakness resulting from the continuing failure to

consider women and, consequently, the sex variable in such theory.

This failure is more than merely methodological, precisely because it means that purportedly general theories of criminal deviance are now no more than special theories of male deviance. This is no small or easily correctable problem. Its solution does not depend simply on more studies of female deviants, on adding a corollary here or a specification there in the current special theories of male criminal deviance and then applying them to women, or on simply reevaluating the current evidence. The solution, or at least its beginnings, as I shall try to point out, most probably lie in the realization that our present conceptual blindness, like the phrenologist's, is deeply rooted in everyday assumptions about *who does what, including deviance*, in a society. Ironically, it is the distribution of these background norms about deviance which, I believe, at once accounts for our professional failure to include women in theories of criminal deviance and, more importantly, provides the single strongest causal account of the empirical differences in male and female criminality.

Such differences are striking indeed: sex appears to explain more variance in crime

* The author wishes to thank Gary D. Hill especially for his advice and encouragement. Thanks are also due other colleagues at the University of Massachusetts at Amherst, several anonymous ASR readers and Morris Zelditch, Jr. for their useful comments on this manuscript.

across cultures than any other variable. This appears so *regardless* of whether officially known or hidden ("true") rates of crime are indexed (Harris, 1976).¹ It is also worth stressing that, with the exception of age, the major social-structural predictors hitherto built into various theories of criminal deviance—class, race/ethnicity, area, and intact family background—are all strongly multicollinear. Sorting out their independent and interactive effects on crime has proved extremely difficult. This empirical morass has been paralleled by a theoretical one involving variations on the theme of structural disadvantage. However, the sex variable, to which virtually no attention has been paid, is only a trivial covariate of these major social-structural variables. The potential theoretical and empirical strategic advantages of this observation clearly have been neglected.

The sex variable potentially provides the clearest of all sociological beginnings in criminal, if not more general deviance theory (that the absolute, though perhaps not relative importance of the sex variable in predicting crime has varied and will continue to vary from time to time and place to place is an issue to which I will return). Unfortunately, however, deviance theorists have, *for all practical purposes*, focused on that part of the social landscape producing the highest criminal yield—males. Similarly, as the Secret Service agents guarding the American president's life traditionally have been tied to monitoring potential male assassins (and only through recent events have had to perhaps literally double their efforts by looking for potential female assassins as well), so too have sociologists been tied to monitoring and theorizing only about male criminal deviance.

For practical purposes akin to those of Mills' (1942) "professional social pathologists," this tie is one thing. For theoretical

purposes, however, it is quite another. Commitment to males only has meant the unwitting trade of general criminal deviance theory for the gain of practical special theories tied to practical everyday interests and expectations. For theoretical purposes and, if we are to believe in the importance of theories, rather ironically for *effective* practical purposes as well, the omission of the sex variable in deviance theorizing is tantamount to the guarantee that we can see neither the forest *nor* the trees.

In what follows, I shall examine what are commonly taken to be the major paradigms in criminal deviance and argue that the inclusion of the sex variable has dire effects on some of these paradigms, but less dire effects on others. Regardless of these consequences, it will be stressed that existing theories ought no longer be considered general theories unless and until they not merely "take account" of the sex variable but, instead, start with it. This issue will be addressed in the particular form: how, theoretically, can the sex variable be brought to bear as a potential distributor of the major conceptual elements in contemporary criminal deviance paradigms? One of the major goals of the analysis will thus involve identifying a parsimonious set of conceptual elements to describe such theories. These elements will be used to develop a propositional notation both specifying the theories and providing the basis for examining them once the sex variable is introduced.

A second major goal will be to locate what I consider the primary conceptual target of labeling theory in "*true*" and not, as presently conceived, in "*hidden*" rates of deviance. This viewpoint will be clarified through developing the outlines of what I will call "a functional theory of deviant type-scripts"; toward this goal, it will be argued that the theoretical notion of greatest potential use in the necessary reconstruction of deviance theory is not one involving the idea of means or of ends or of perceived opportunity but, rather, is one involving the idea of self-attribution. This claim will be seen as consonant with the general labeling perspective on deviance on the condition that the perspective

¹ This point is made with respect to American data. When data from less industrialized societies are considered, the point is more striking. Prior to modernization, data from third world societies yield sex ratio ranging from 900:1 to more than 20,000:1 (Nettler, 1974).

be revised and refined in several major respects.

THE MAJOR ELEMENTS IN CRIMINAL DEVIANCE THEORY AND THE CONSEQUENCES OF INTRODUCING THE SEX VARIABLE

A major problem in evaluating sociological theories often lies in the lack of specificity of the key conceptual terms in the theories. In order to specify the major criminal deviance paradigms for present purposes, I identify what I believe to be a theoretically parsimonious set of four conceptual elements, the social distributions of which are seen as providing the basic concerns of criminal deviance theory. These elements or their variants are used with great regularity in contemporary social psychology and together are held to be basically sufficient for developing a propositional notation by which the paradigms in question may be specified, potentially operationalized and empirically assessed.

The first such element is *Goal Utility*: the subjective reward characteristics or value of a particular type of behavior choice *if* it pays off. As such, goal utility (GU) is the contingent or possible (extrinsic) payoff value of choice—in frequent sociological usage, an “end.” Usually, but not necessarily, this kind of utility has extremely high social communality and may be easily traded. High communality utilities, such as money or material goods, may be thought of in Weber’s (1947) terms as having “primary value” in a society.

The second element is *Behavior Utility*: the subjective reward characteristics or value of a particular type of behavioral choice (intrinsically) received *when* the behavior is performed—in frequent sociological usage, a value inherent in behavior as an “end in itself.” As such, behavior utility (BU) necessarily is pegged to one type of behavior rather than to another. Usually, but not necessarily, this kind of utility has weaker social communality than goal utility and is not easily traded. Relatively high behavior utility, such as that attached to “good sportsmanship” or “getting high,” may be thought of in Weber’s

terms as having “secondary value” in a society.

The third element is *Probability*: the subjectively perceived chance of attaining utility (GU or BU). As such, probability (P) reflects the perceived chance that a particular type of behavioral choice will lead to gratification. The last element is *Self-Attribution*: an actor’s subjective inference that self is a member of a class of actors “likely to perform behavior Y.” As such, self-attributions (SA) are meant to reflect the subjective sense that because one is a member of the class of actors X, one expects oneself to choose a particular type of behavior at a higher rate than members of the class non-X.²

Having defined these terms, we turn to two questions: (1) how are the terms distributed in contemporary criminal deviance paradigms and (2) what happens theoretically when the sex variable is introduced in the analysis? It should be remembered that *the theories we will examine are claimed to be general. As such, their scrutiny cannot therefore be vitiated by the counterclaim that they apply only to men.*

Probability

The probability element represents perhaps the major conceptual unit in criminal deviance theorizing. It is usually tied to notions of goal utility or primary value, to consequent assumptions that goal utility is a fixed sum in a society and, thus, to theorizing about economic or property-related crimes. Two basic variants on this theme are encountered in theories of structured strain and differential opportunity. In each case, one or both of two kinds of probability, the perceived probability of obtaining goal utility given legitimate (L) means (i.e., $P(GU|L)$) and the perceived probability of obtaining goal utility given criminal (C) means (i.e., $P(GU|C)$), are seen as distributed by social-structural factors.

Structured strain. In this basic variant,

² Alternatively, this notion may be expressed in terms of subjective probability (P). Thus, given the newly acquired self-attribution that one is “criminal” as opposed to “straight,” P of criminal behavior would be expected to increase.

the probability of attaining goal utility by legitimate means is hypothesized as distributed by such social-structural factors as class or caste (cf. Merton, 1968). From this viewpoint, actors with objectively lower chances of attaining goal utility via legitimate means are very likely to perceive these low chances realistically. It is also characteristically assumed from this viewpoint that such actors have relatively higher perceived access to goal utility via criminal behavior. In themselves, these two conditions are not seen as sufficient to produce criminal behavior in structured strain theory. A second condition must be added—that actor find little or no intrinsic utility in the choice of legitimate means (i.e., maintain low $BU|L$). Consequently, it is reasoned that:

when

$$(1) P(GU|C) > P(GU|L)$$

(and where $P(GU|L)$ is distributed by social structure)

and

$$(2) BU|L \text{ is low}$$

then

$$(2) \text{Probability of } C > \text{Probability of } L.^3$$

It is extremely important to observe that, in this paradigm, it is only the probability of goal utility via legitimate means which is seen as systematically distributed by social-structure, and *neither* the probability of goal utility via criminal means *nor* the behavioral utility attached to legitimate means. It is tacitly assumed, that is, that *everyone* in a society has equal access to GU via C, and that little can be predicted about the structural distribution of commitment to legitimate behavior utility.

In order to maintain its logical structure once the sex variable is considered, structured strain theory would seem to require that its major element, $P(GU|L)$, be distributed by sex. From this viewpoint, how-

ever, the theory becomes counterfactual: since women appear to have lesser access to goal utility via the array of legitimate opportunities available than men do, women should show a higher crime rate (if only for economically related crimes) than men. Clearly they do not.

Differential opportunity. In this variant, often confused with structured strain (but actually overlapping it), *both* the probability of attaining GU by legitimate behavior *and* that of attaining GU by illegitimate behavior are seen as distributed by such social-structural factors as class, caste, ethnicity and area (cf. Cloward and Ohlin, 1960). From this viewpoint, as that of structured strain, actors with low objective access to GU via L are assumed to have realistic perceptions. As Short et al. (1965) have pointed out, once "low access" actors review their chances for goal utility via legitimate behavior, differential opportunity theory predicts a next step involving the cognitive review of perceived chances for goal utility via criminal means. Where this latter perception was invariantly distributed for structured strain theory, for differential opportunity theory it is seen as distributed by such variables as class, caste and neighborhood. Put simply, the perceived availability of primary values through criminality is now understood to vary by members' locations in social space. Consequently, it is reasoned that:

when

$$(1) P(GU|C) > P(GU|L)$$

(and where both terms are distributed by social structure)

then

$$(2) \text{Prob } C > \text{Prob } L.$$

Since now the probability of GU via criminal behavior cannot be assumed to be uniformly high for everyone, a more reasonable accommodation of the sex variable is possible. To make the strongest case for this viewpoint, where women have traditionally had lower access to GU via legitimate behavior than men, it would seem they have also been traditionally locked into the home and, consequently, out of access to criminal means. Thus, while women may generally maintain lower lev-

³ The terms "Probability of C" and "Probability of L" refer to objective or performance probabilities (henceforth, Prob C and Prob L) rather than to subjective probabilities (P). Though throughout the rest of the paper I will rely on deductive statements (Prob C > Prob L), propositions might alternatively be expressed as: the greater the X the greater the Y (e.g., Prob C).

els of $P(GU|L)$ than men, they also maintain even lower levels of $P(GU|C)$ than men. Given this, the differential opportunity approach would seem capable of accommodating the sex variable.⁴ Two major caveats, however, suggest otherwise.

First, for women the probability of goal utility or primary value through criminal means may well be lower than that for men because of women's traditional location in the home. This limitation, however, should *not* mitigate substantially the probability of committing violent crimes. As official and hidden data reveal, the opposite is true. Where we would on the basis of differential opportunity theory expect a lower sex ratio for crimes of violence than for economic crimes, the sex ratio for violent crimes is approximately *double* that for property crimes. Clearly, in its own right, the differential perception of criminal opportunity cannot account for this.

Second, even if economic crimes are considered the only type of crime within the theoretical purview of the differential opportunity perspective, there are other hurdles the perspective must face. In recent years, the sex ratio has decreased markedly for property crime arrests in general, and for white-collar economic crimes in particular. Although this change has, in effect, been interpreted as support for differential opportunity theory (e.g., Simon, 1975), the sex ratio for these crimes has dropped more quickly in the past few decades for people under 18 than for those over 18 (Harris and Hill, 1976). This observation would seem to suggest quite strongly that the opportunity to commit economic (including white-collar) crimes, assuredly greater for those over 18 rather than under 18,⁵ does not successfully account for age variance in the changing sex

differential. For, if the differential opportunity approach were correct, we should clearly expect a more marked decrease in that differential for those over 18 and in the labor force than for those under 18.

Behavior Utility

Theories built on the distribution of behavior utility are, in effect, concerned with social variance in secondary or special values intrinsically attached to specific classes of behavior. In the pursuit of desired goal utility or simply as an end in itself, behavior utility becomes a potential discriminator in the choice of one type of behavior over another. From this viewpoint, and following Cancian's (1975) line of argument about norms, behavior utility provides the affective core of "normative commitment" and the consequent gratificational basis for acts which document social identities. The social communality of behavior utility, especially as it concerns the binary choices of legitimate and criminal behavior, is of particular interest to deviance theory. How much intrinsic satisfaction, for example, is gained by different classes of actors for this particular act of conventional behavior, such as returning excess change at the cash register, or for that particular act of criminal behavior, such as stealing a car? Three basic paradigms which focus on the distribution of behavior utility are differential association, subcultural difference and control theory.

Differential association. A major feature distinguishing differential association from subcultural and control theory is its absolute neutrality with respect to probability considerations. Here, concern lies purely with utility. Though the differential association approach potentially has much to do with goal as opposed to behavior utility, I include it here because of its ability to illumine issues involving the relatively lower social communality of behavior utility than goal utility. In this variant of BU theory, the focal concern rests on "definitions" favorable to crime. Because this idea is not specified, it is both problematic and of broad potential significance. I will interpret the notion to mean subjectively favorable perceptions of utilities as opposed to

⁴ Simon (1975) appears to make this argument, for example, in explaining changing patterns in female arrest rates.

⁵ This rests on the assumption that there are more opportunities for occupation-related economic crimes for women over 18 and on the additional assumption that the opportunity to commit larcenies (such as shoplifting) is not significantly different for older females tied to households as opposed to younger females not so tied.

costs or disutilities (D) tied to criminal behavior. Thus, when Sutherland and Cressey (1966:81) speak of the "excess of definitions favorable" to crime "over definitions unfavorable" to crime, I understand this to mean the ratio of (a) goal+behavior utility via criminal behavior to (b) goal+behavior disutility via criminal behavior. Thus, it is tacitly reasoned:

when

$$(1) (GU|C+BU|C) > (GD|C+BD|C)$$

(where both terms are distributed by "association")

then

$$(2) \text{Prob } C > \text{Prob } L.$$

Differential association theory thus argues a simple cost-benefit analysis of criminal choice, maintaining that on the individual level the outcome will vary by actor's "association" with people and/or ideas on one end of the utility/disutility calculus or the other. In reality, this position is that of classical utilitarian criminology, with few conceptual gains and a large loss of precision. Differential association theory, moreover, leaves unspecified the social-structural distribution of its theoretical elements, except for the sociologically uninformative notion of "association," and thus bears little risk of falsification. Precisely because of its unrestricted character, the ability of differential association to stand once the sex variable is brought in cannot be questioned. From this viewpoint, the issues are: (a) do men have higher ratios of favorable to unfavorable definitions of crime than women and (b) if so, how and why? My suspicion is that the answer to the first question is "yes, men do." But this assumption neither locates one in any particular theoretical camp, nor helps in keeping the etiological question from being begged.

Subcultural differences. In this variant on the theme of behavior utility, the strength of BU tied to criminal behavior (though occasionally the strength of BU tied to legitimate behavior as well) is seen as distributed by such social-structural factors as caste, class and age (cf. Cohen, 1955; Sykes and Matza, 1957; Miller,

1958).⁶ From this viewpoint, subcultures formed on the basis of salient social identities have the power to construct realities incorporating, disavowing or neutralizing mainstream behavior utilities (the affective core of "normative commitment"). One critical factor separating subcultural difference from differential association theory is the former's implicit focus on comparative levels of BU via C and BU via L for individuals. The second, more important factor lies in subcultural theory's concern for probability. In these terms, a strong point of the subcultural approach rests in the functionalist assumption that low perceived access to legitimate goal utility (i.e., low $P(GU|L)$) leads classes of structurally disadvantaged actors to generate higher levels of behavior utility for criminal choice and/or lower levels of behavior utility for legitimate choice. Consequently, it is reasoned that:

when

$$(1) P(GU|C) > P(GU|L)$$

(where $P(GU|L)$ is distributed by social structure)

then

$$(2) BU|C > BU|L$$

(where $BU|C$, and possibly $BU|L$, is distributed by subcultural access)

thus

$$(3) \text{Prob } C > \text{Prob } L.$$

In order to maintain its coherence once the sex variable is considered, subcultural difference theory would need to argue: (a) there is a vast female and/or male

⁶ Cohen's (1955) theory really represents a special case of subcultural difference theory. The psychodynamic mechanism of "reaction formation" is relied on to argue that those with low access to GU via L will cognitively transform that utility, along with conventional utility tied to legitimate behavior (BU via L), to something actively *disvalued*. Those undergoing this transformation should be expected to try to act anti-thetically to GU and BU via L—to engage in behavior somehow negating that utility which cannot be had. Artificially, this behavior is defined as criminal (e.g., vandalism). The theory is unusual, especially in that it posits systematic cognitive relations between probability and utility.

subculture (or a vast set of such subcultures) and (b) this subcultural variance distributes the major element of $BU|C$ and, possibly, the minor element of $BU|L$. Since from this viewpoint, however, subcultures represent the responses of the disadvantaged to blockage from goal utility via legitimate means, we should expect women to develop higher levels of criminal, relative to legitimate, behavioral utility than men and, consequently, higher levels of criminality than men. Clearly, the data indicate the exact opposite.⁷

Control. In this last variant of BU theory to be considered, preference for behavior utility via legitimate behavior is always assumed to be unequally distributed, but not usually by social structure. In the version of control theory advanced by Nye (1958), it is implicitly understood that it is *always easier* to attain goal utility via criminal than legitimate means (the idea of the "fast buck"). This assumption forms a crucial backdrop for the question: why, then, do people ever choose the straight and narrow? For control theory the answer lies in the intrinsic behavior utility of legitimate choice. Hirschi's (1969) version of control theory postulates that commitment to "conventional" activities (such as sports) and "conventional" others (such as parents) provides the major social distributor of $BU|L$. Though one is not sure of how such commitment, in turn, is distributed by social-structure, it is consequently and tacitly reasoned that:

when

(1) $P(GU|C) > BU|L$

(where $BU|L$ is distributed by conventional "commitment")

(2) regardless of $P(GU|C)$ versus $P(GU|L)$ comparisons
and/or

$GU|C$ versus $GU|L$ comparisons,

then

(3) $\text{Prob } C > \text{Prob } L$.

⁷ If subcultural difference theory were to drop the functionalist claim that probability considerations involving low access to GU via L lead to the formation of deviant subcultures, it might stand in a better theoretical position with respect to the inclusion of the sex variable.

The major theoretical tension in the control paradigm is *across* the *metrics* of BU via L and of $P(GU|C)$: if the pull toward criminality is strong (which is always so because the probability of goal utility via crime is always assumed to be high), then the only possible counterforce resides in the extra-goal utility and extra-probability considerations inherent in commitment to legitimate behavior utility. It is worth noting that, in addition to having little to say about the social-structural distribution of behavior utility for legitimate behavior, control theory also has little to say about the social-structural distribution of behavior utility for criminal behavior (which term does not even count as an element in control theory). For this paradigm to claim generality and handle the inclusion of the sex variable, it would have to be argued that for juveniles *and* adults, sex distributes higher levels of commitment to conventional activities and others for females than males *and*, as a consequent function of this, higher levels of legitimate behavior utility for females than males. Though, perhaps not contraindicated by much existing research or theory, the assumption that females are more committed to conventional activities than males is not, I think, a strong one, especially when adult males and females are considered.⁸ Be this as it may, while control theory potentially provides a reasonable account of the sex difference in criminality, as differential association theory, it is still incomplete for it begs the questions, how and why?

Self-Attribution

Theories built on the distribution of self-attribution can be clearly separated from the preceding ones. Where all the preceding theories rely on some notion of subjective rationality or calculation in the production of criminal choice, theories built on the notion of self-attribution need not do so. What is at stake in such theories,

⁸ In a study of college students, Silberman (1976) reports *no* significant difference between males and females on levels of "moral commitment"—despite the simultaneous finding that the males report significantly higher rates of criminal offenses than the females.

instead, is the question of whether—through rational or extra-rational considerations—an actor perceives herself or himself as “the type of person expected to do L or C.” From this viewpoint, self-attribution which produces deviance has the propositional logical form, “since I am a member of the class of people ‘X,’ then I expect myself to produce more of behavior ‘Y’ than nonmembers of ‘X.’” This group of theories we identify by the variants “containment” (or self concept as insulator) and “labeling.”

Containment. In this version of self-attribution theory, actor's perceptions of self as (a) a person likely to get into trouble with the law and (b) a person not likely to get into trouble with the law are seen as distributed by socialization practices (Reckless et al., 1956). In a major respect, containment theory parallels control theory. Both assume an *a priori* pressure towards deviance which, if not checked, would result in a visibly high choice of criminal behavior. Where control theory, however, finds the source of the individual pressure toward criminal deviance in invariant probability considerations (see above), containment theory finds such pressure distributed by neighborhood or area.

Containment theory originally was introduced in order to close an apparent gap in probability theorizing, that is, to explain why some slum boys rather than others became criminal. As such, containment theory implicitly holds that the “criminal impulse” (either P or U, one cannot be sure) is distributed by neighborhood. But, as would also be the case for control theory, explaining the impulse to deviance is insufficient in accounting for the nondelinquent in the high delinquent area. One also needs to account for the checking of the impulse. Thus, in an equally important comparison, where control theory finds the “check” on the criminal impulse in the individual's intrinsic commitment to legitimate behavior utility, containment theory finds a parallel “check” in self-attributions which vary by socialization practices. Such attributions have the form $S \supset L$ (“self (S) implies legitimate behavior”) or $S \supset \sim C$

(“self implies noncriminal behavior”). Thus, it is reasoned:

when

- (1) $P(GU|L)$ or $GU|L$ is low
(where either term is distributed by neighborhood)

and

- (2) $S \supset C (=SA)$
(where SA is distributed by socialization)

then

- (3) $\text{Prob } C > \text{Prob } L$.

In a (social-psychologically) more rigorous form and given a more fully articulated approach to the social-structural distribution of its theoretical elements, containment theory would seem to provide a potentially powerful basis for handling the inclusion of the sex variable. Self-attributions are very clearly tied to and distributed by sex in this, if not in all societies. One such attribution with extremely high social communality may very well be the belief, held by men and women, that men are likely to get into trouble with the law; another may well be the belief that women are not. This approach, consonant with the reasoning that behavioral choice involves the extra-rational alignment of behaviors with self-perceptions (cf. Bem, 1967), would provide a “motivational” account of sex differences in criminal deviance free of the problems encountered in probability theories, fully in line with existing data and theoretically capable of subsuming control theory's necessary assumption that women maintain higher levels of legitimate behavior utility than men. (If, that is, women maintain higher levels of $BU|L$ than men, this is an affective artifact of self-attribution rather than its cause.) On the other hand, while containment theory may well offer the best theoretical elements so far for understanding the possible “how” of the etiology of sex variance in crime, it has little to say about the “why.”

Labeling. In this variant on the theme of self-attribution, actor's perception of self as a person likely to commit deviant behavior is seen—unlike the view in containment theory—as distributed by social structure, though in complex fashion. Two

kinds of interrelated social-structural phenomena form this distributive basis for labeling theory: (1) actor's relative social power or status and (2) contingent on this, actor's ability to counteract potential contact with official agents of social control. Crucial here is the assumption that what is distributed by such processes is *not* what Lemert (1951) has called "primary deviation"—in which *everybody* engages—but, rather, is "secondary deviation"—a form of deviance providing the organizing principle of behavior and in which only *some* engage. From this viewpoint, the proper criterion variable in the analysis, secondary deviance, is seen as a direct function of contact with, and labeling by agents and agencies of control. The power to resist such contact is argued by labeling theorists to vary by correlates of social stratification, including caste, class and age. The intervening process between official contact and secondary deviance is to be found, from the labeling viewpoint, in the processually induced self-attribution that self (S) is a member of the class of people called deviants and, since this is the case, in the consequent alignment by S of deviant actions with deviant self-attributions. With respect to the criterion phenomenon of secondary (and *not* primary) deviance, it is thus reasoned:

when

(1) $S \supset C (=SA)$

(where the term is distributed by the interaction of S's social status and contact with social control)

then

(2) $\text{Prob } C \supset \text{Prob } L$.

Containment theory locates the source of self-attributions which hinder or facilitate deviance in a rather amorphously identified area of "socialization" orthogonal to social structure; labeling theory locates the source of the deviant self-attribution in the interaction between actor's social power and contact with agents of social control. From this viewpoint, conventional labeling theory might seem capable of accommodating the sex variable through the assumption that women have less contact with agents of social control than men,

consequently weaker deviant self-attributions and, finally, lower rates of criminal behavior. The problem, however, is that, in the conventional sense, men have greater social power than women. Labeling theory would therefore seem obligated to the expectation that men ought to have greater ease in negotiating official labeling and, thus, to the counterfactual prediction that men have lower rates of criminal deviance than women. As I shall try to argue directly, I believe this otherwise fatal problem for labeling theory is tied to its usual and unnecessary insistence that only secondary, rather than primary deviance is of proper theoretical concern, and that actor's contact with social control is best predicted by actor's social power rather than "type."

LABELING THEORY REVISED: TOWARD A GENERAL FUNCTIONAL THEORY OF DEVIANT TYPE-SCRIPTS

I contend that any powerful general theory of criminal deviance, if not deviance more broadly, is a theory involving the stratification of behavior and identities. From this viewpoint, the functional preservation of social dominance may be seen as resting on the assignment of readily identifiable social "types" to classes of social locales and locale-specific roles. In American society, the assignment of blacks to the ghetto, women to the home and poor to the factory represent examples which have met the function of preserving white, male, middle-class dominance. Homologous legal, educational and occupational structures support such assignments and, at the level of group cognition, provide powerful expectancies by which actors come to assign themselves and others to limited classes of behavior according to social "type." Such expectancies—which specify broad behavioral sequences as well as type-to-role linkages—are referred to here as *type-scripts*. It is maintained that these scripts have important extra-logical implications, held with high social communality with respect to the perception of classes of behavior it is *likely*, *possible*, *unlikely* and *impossible* for particular types of actors to perform.

Unlike scripts for the theatre, which very precisely delimit word and action for a role but which do not specify who is to play it, type-scripts are seen not as delimiting the specific content of social roles but as specifying the types of actors who are to play them. This is not to suggest that type-scripts align a type of role with only one type of actor, or a type of actor with only one role. Rather, it is to suggest that such background expectancies align particular sets of actor types with particular sets of social roles.⁹

From the objective viewpoint, type-scripts are "normative": regardless of the social distribution of affect held for them, they would appear to have relatively high cognitive communality across both dominant and dominated groups.¹⁰ From the subjective viewpoint, type-scripts are informative since they provide not only a limited array of role choices but also the most salient bases for a limited set of possible social identities. In these terms, be-

sides aligning types of actors with possible classes of legitimate behaviors and identities, type-scripts also are seen as aligning types of actors with possible classes of deviant behavior and identities. One dominant order-maintaining function of type-scripts, then, involves specification of what types of actors are to commit what types of deviance in a society and—perhaps more illuminating—what types of deviance are seen as unlikely or "impossible" for other types of actors to commit.

Several examples illustrate the point. It is strongly type-scripted in American society that street crimes represent the preserve of blacks and the poor. From a somewhat different slant, it is (or was) scripted that it is nearly "impossible" for the highest officials in the land to act criminally. Similarly, and perhaps more relevant to the present analysis, it is (still) type-scripted that it is unlikely or "impossible" for women to attempt assassination, robbery or rape.¹¹

Based on the assumption of role assignment in the interests of the socially dominant, a functional theory of deviant type-scripts would maintain that, over time, deviant type-scripts which preserved dominant interests in particular role arrangements also would be preserved. From this perspective, in order to be functionally effective, deviant type-scripting must meet a special condition: *the existence or filling of*

⁹ It is proposed that this linking function is best seen as probabilistic, continuous and multi-conditional. In these terms, it would be possible to observe the conditional probability level a group held *vis à vis* the chances that a particular type of actor X—such as a woman—would hold a particular type of role Y—such as a bank presidency (i.e., the conditional "front" probability, $P(Y|X)$); or that the role Y would be held by the actor X (i.e., the conditional "back" probability, $P(X|Y)$). As suggested, such perceived probabilities are best approached as multi-conditional: while most members of this society undoubtedly hold a very low probability that a bank president would be female, there is undoubtedly a still lower perceived probability assigned the type-script of a bank president being both female and black. (In combination, however, conditional probabilities may be interactive rather than simply additive.)

¹⁰ It is important to recognize that the aligning linkages provided by type-scripting may be at considerable variance with empirical probabilities. As anonymous reports on criminality imply, "true" rates of deviance for given types of actors are often out of line with public representations of these rates. This may be as true for public under-representations of white-collar crime as it appears to be for white, middle-class delinquency. Incongruity between alignment probabilities in type-scripts and actual empirical probabilities is not seen as a random phenomenon but, rather, as systematically related to the maintenance of dominant interests by agencies of social control.

¹¹ As recent attempts on the life of the American president have pointed out, it is possible if not easier for women to engage in assassination. Similarly, it is clearly as possible for women to commit robbery. Though most people are aware of the "equalizing" effects of handguns, the countervailing script against female robbery has it that females would be overpowered in robbery attempts, even if they carried guns. The power of this deviant script or, rather, of its absence is strong—so strong as to preclude the realization that, even if strength were the issue, women can rob other women. Perhaps the strongest illustration of deviant scripting (or its absence), however, involves the notion of rape. Present scripting holds that rape involves vaginal penetration. On this assumption, male rape is ruled out by definition. Clearly, alternative sexual violations consonant with the more general moral principle of rape cannot be ruled out as impossible for females to commit against males or, for that matter, against females.

legitimate roles vacated by those actually assigned deviant status must not threaten the institutional hegemony of the socially dominant. Should this role-replacement condition not be met and the threat arise otherwise, the potential for broad societal script disarray would be great and the status and power advantages of the dominant would be severely challenged.

In these terms, ghetto males lost from legitimate roles (e.g., fatherhood) to prisons through crime—though a real loss to the black family and a potential loss to the abstract interests of the commonweal—are by no means a threat to the ongoing economic, political and symbolic interests of the socially dominant. (As literate whites can now testify, family structure in the ghetto is “matriarchal anyway”—the vacated role will presumably be filled easily by the black woman.) Similarly, given high rates of blue-collar unemployment, social members lost from blue-collar roles to prisons through crime are by no means a threat to the economic, political and symbolic interests of the socially dominant. (As many literate social scientists can testify, work in blue-collar and intensive labor occupations is to a high degree “functionally interchangeable.”) In neither of these cases does the existence or filling of the vacated role pose a threat to dominant interests.

The reassignment of women from homes to prisons, however, does *not* meet the role-replacement condition. Male dominance in occupational, educational, political and legal institutions is not served by allowing the development of type-scripts which lead to putting women in jail. Rather, the prime structural mainstay of male institutional hegemony has been the continued assignment of females to the home and to the role of homemaker. Assignment of females to this locale, a modal empirical feature of every class and ethnic group within this and almost all societies has had, among other structural implications, the major virtues of eliminating half the competition, of keeping labor supplies shorter and (male) wages higher than they would otherwise be, and of allowing males the full-time opportunity to manage extra-

familial institutional control. The regular and routine assignment of females to prisons, on the other hand, would appear to challenge this advantage severely through the development of increased rates of one or more major disequilibrating outcomes: (1) the breakup of the nuclear family, (2) the maintenance of the nuclear family only with grave financial burdens entailed in hiring a full-time role replacement for the female and/or (3) the partial or full-time withdrawal from the occupational sector of males so affected.¹² It is thus argued that it is not in the interests of male dominance to allow the development of deviant type-scripts for women, both among secondary agents of social control (such as police and courts) and, at a more fundamental level, among primary agents of social control (such as parents and teachers).

As outlined in these terms, the functional regulation of deviant role incumbency through the regulation of type-scripts is seen as providing a basis for distinguishing, in the most ironic sense, deviant behaviors and identities which are expected, functional and socially articulated for certain actor types from behaviors and identities which are anomalous, dysfunctional and socially inarticulate for other actor types. (Thus, where blacks and poor may be said to “become criminal,” types for whom deviant scripts are unwritten may be said to “become anomalous.”)

The theory outlined here extends labeling theory in several major ways. First, it offers a social-structural account of who and what is to be considered deviant and why.¹³ Second, it argues that the back-

¹² The threat to male hegemony posed by reassigning females from the home to prisons is not argued as varying by caste or class. It should be expected, however, that on the basis of caste and class power differentials in resisting detection, incarceration, etc.: (1) black and/or poor females will be assigned to prisons more regularly than white and/or middle-class females and (2) the hegemony of the black and/or poor male will be more threatened by such assignment than that of the white and/or middle-class male.

¹³ It may be objected that the development of type-scripts, though given an explanation here in terms of “why,” is not explained in terms of “how.” Though this apparent gap is often seen as

ground expectancies for deviance contained in type-scripts have social communality extending across the boundary between the dominant *and* the dominated. Third, in assuming this "normative" distribution, the theory maintains an etiological scenario at the individual level. In these terms, scripts for who and what is to be considered deviant become the direct basis for deviant self-attributions. Thus, it is important to realize that the proper major target of a functional theory of deviant type-scripts is *not* secondary deviance as labeling theory would have it but, rather, is *primary deviance per se*. From this viewpoint, deviant self-attributions actualized through the perceived linkage between social "type" and deviant type-scripting become the "motivational" basis for engaging in deviant behavior *independently* of direct contact with official agents of social control.¹⁴ Finally, in hypothesizing the direct impact of deviant self-attributions on (primary) deviant behavior, a functional theory of deviant type-scripts need not forego attention to the role of official social control. Rather, contact with

official agents may be seen as homologous to previous type-scripting and, consequently, as providing: epistemological reinforcement for deviant self-typing at the individual level, stronger attendant deviant self-attributions and further organization of personality through pressure to accept the master trait of "deviance" (secondary deviance).

The theory outlined here would seem capable of starting with the sex variable and accounting for the very high amount of empirical variance it "explains" in official *and* hidden criminality. Since the theory need not be restricted by the specification of concrete socially-dominant groups, it is historically and cross-culturally flexible.¹⁵ In these terms, despite the ubiquity of male dominance historically and cross-culturally, the degree of such dominance may easily be measured independently of sex ratios in criminal deviance and, at a minimum, the two expected to covary. Thus, even though the marked sex ratio in criminality may disappear in time, and more quickly so in post-industrial societies such as ours, the power of a general functional theory of deviant type-scripts would not be contingent upon such an occurrence.

a problem indigenous to functionalist arguments, the reader is cautioned to realize that this is properly a question of how *any* norms consonant with a given social order emerge. This general question is beyond the scope of the present paper.

¹⁴ It is not argued here that all members of a social type assigned deviant type-scripts (e.g., males, blacks, adolescents) engage in primary deviance at the same rate. On the one hand, it is not maintained that a given type is scripted for only one role. On the other hand, the issue is more properly one of explaining deviant *rate* variance across social types. Attempts to explain rate variance within types—analogue to the attempts by Reckless et al. (1956:16) to explain the existence of the nondelinquent slum boy—may, in part, be dealt with in the present context in terms of self-attributions which cross-cut and mitigate deviant type-scripts. The bulk of this mitigating effect is seen as a function of cross-cutting role alignments—and consequent self-attributions—based on such social-structural typologies as caste and class. From this viewpoint, and as opposed to the position of Reckless et al. (1956), the overt message, "you are a good boy, and good boys don't get into trouble with the law," is not nearly so subjectively important and sociologically significant as the covert message, "you are a white boy, and white boys don't get into trouble with the law."

CONCLUSIONS

That the sex variable in some form has not provided the starting point of all theories of criminal deviance has been the major failure of deviance theorizing in this century. In all, it appears to provide the single most powerful predictor of officially and unofficially known criminal deviance in this society and almost certainly in all others. Had the phrenologists realized this, and had they measured waists instead of skulls, they too might have discovered the need to begin their theorizing on the basis of gender.

As a variable, however, sex is categorical and, consequently, primitive. Whatever

¹⁵ Though our critique has been of theories of criminal deviance, the functional theory of deviant type-scripts outlined here need not be restricted to criminal deviance.

the theoretically useful correlates of this term and whatever their etiology, I have argued that understanding the role of gender in producing deviance remains the point toward which all deviance theorizing needs to be directed. This is not simply a theoretical problem. Strategies geared to the reduction of crime which do not face this issue squarely either must assume a fixed genetic basis for the sex difference in criminality (which, among other reasons, makes little sense given the simple observation of sharp drops in sex ratios as societies industrialize) or must continue to face the absurdity of developing, by analogy, a medical art based solely on the study of the "ill," never looking at the "well."

Yet this is not an easy thing to see. Shared representations of social reality which have to do with crime and typifications of deviance generally have at once precluded sociological awareness of the necessity of including sex in deviance theorizing and, at the same time, undoubtedly played a major sex-specific etiological role in the creation of deviance itself. Put simply, dominant typifications about what kinds of actors "do" criminal behavior—typifications which have served dominant male interests and have been held by both sexes—have played a crucial dual role in, on the one hand, keeping sociologists from seeing the sex variable in criminal deviance and, on the other, keeping men in crime and women out of it. The functional theory of deviant typescripts presented here in outline would, in principle, account for these parallel outcomes.

Though I have argued that it is unlikely or unreasonable to expect that the bulk of contemporary criminal deviance paradigms are capable of accommodating the sex variable as the starting point of the analysis, it has not been my intention to claim that this has been demonstrated. Of necessity, the critical argument has been developed with respect to crime generally and not to particular kinds of crime, has carried its own theoretical specification, and has been made speculatively when in the end, such issues are an empirical mat-

ter. All these issues lend themselves to ready debate. Yet, however valuable the critique and theory outlined here may be, given the present state of affairs in deviance theory, it is crucial that attempts be made to address the issues raised. It is my strong conviction that historically consuming questions in deviance theory—especially those involving caste and class—will be best addressed only *after* such attempts are made.

NORMAL HOMICIDES AND THE LAW *

VICTORIA LYNN SWIGERT

College of the Holy Cross

RONALD A. FARRELL

State University of New York, Albany

American Sociological Review 1977, Vol. 42 (February):16-32

This work focuses on the effects of a popular conception of criminality in the adjudication of homicide defendants. Data from a sample of persons arrested for murder suggest that the stereotype of the violent offender, the "normal primitive," constitutes an official imagery within which legal decisions are made. Path analytic techniques indicate that conformity to the criminal conception, along with the social class of the defendant, has significant consequences for the assignment of public counsel, denial of bail and a plea of guilt before the judge. Lack of access to legal resources, in turn, produces the more severe convictions awarded by the court.

The differential legal treatment of criminal offenders constitutes one of the most controversial areas of study in contemporary criminology. Allegations of racial discrimination or class bias in the judicial system have prompted continued debate and investigation of the issue. Yet the search for patterns of discretionary treatment has generated contradictory findings. Studies of police administration, bail procedures, prosecution and defense, jury selection, and final disposition, while prolific, have failed to surface a definitive statement concerning equality of justice in the United States.¹

The use of class and race as the primary criteria against which legal treatment has been evaluated may be responsible for the disparity of findings evident in the litera-

ture. The criminal justice system is the institutional representation of the "American Creed" (Myrdal, 1944) of equality for all. With many stages of the judicial process open to public inspection and legal sanction, violation of this principle through manifest class or racial discrimination would seriously undermine the collective myth.

Given a society characterized by an official commitment to equality before the law, the selective use of discretion in the legal system might better be examined along alternative lines. In this regard, it may be noted that law enforcement and adjudication are interpretive processes. At each stage, legal authorities must assess the offender and the offense for evidence that official sanction is warranted. Such evaluation and interpretation may be guided, in part, by popular stereotypes of criminality.

Evidence that stereotypes exist in the general population is abundant. People do, in fact, tend to utilize highly stereotypical characterizations in describing deviants.

* Paper presented at the Seventy-First Annual Meeting of the American Sociological Association, New York City, 1976.

¹ Discussions of the discrepant findings evident in the literature may be found in Hindelang (1969) and Swigert and Farrell (1976: ch. 2).

Furthermore, individual descriptions of specific deviations are remarkably similar in content (Simmons, 1965:226). Thus, "the marijuana smoker stereotype emerges as an insecure escapist, lacking self-control and looking for kicks; the adulterer is immoral; promiscuous, and insecure; the homosexual is perverted and mentally ill; the political radical is ambitious, aggressive, stubborn, and dangerous" (Simmons, 1965:228). Such conceptions are perpetuated in everyday interaction and in the mass media characterizations of comic strips, television, newspapers, books, songs and advertising. In this manner, even the very young become familiar with stereotypes, images that continue to be reaffirmed throughout adulthood (Cain, 1964:278-89; Scheff, 1966:64).

Stereotypes not only shape public attitudes and behavior toward deviants, but guide the very choice of individuals who are to be so defined and processed. Persons possessing characteristics associated with the stereotype of a particular deviation are more likely to be identified and reacted to as such (Simmons, 1965:226). Furthermore, since minority groups, lower class persons, and males more closely approximate stereotypic images, these groups are especially susceptible to their application (Simmons, 1965:226; Hess and Mariner, 1975:255).

Such a pattern also may be observed at the organizational level. Thus, popular beliefs about deviants within social control agencies have been found to influence the application of formal labels regarding criminality. It has been noted, for example, that among legal authorities there is evident a belief that certain groups in the population are inherently criminal. This anticipation of law-violating behavior underlies much of the discretionary treatment accorded the black and the poor. The use of violence against blacks and slum dwellers (Westley, 1953), the cursory disposition of urban vagrants (Foote, 1956) and the differential selection of juveniles for treatment (Goldman, 1963; Piliavin and Briar, 1964) illustrate not so much racism or class bias in the law, but a response to a belief that blacks and the poor require rough treatment (Westley, 1953:163), that

obvious destitution implies future criminality (Foote, 1956:310) and that black children are more likely to engage in crime than white children (Goldman, 1963:288).

Given the suspicion concerning the behavior of these groups, encounters of legal authorities with black and lower class individuals are potentially problematic. In such a situation, the decision to invoke legal sanction is a process of determining the extent to which the individuals involved conform to the criminal stereotype. Thus, the arrests and prosecution of juvenile delinquents (Goldman, 1963; Piliavin and Briar, 1964), delinquent bail cases (Skolnik, 1966), shoplifters (Cameron, 1964; Steffensmeier and Terry, 1973) and homosexuals (Farrell and Hardin, 1974) have been shown to be motivated more by the stereotypic appearance of the offender than by evidence of actual criminal behavior; while facial stereotypes of the murderer, robber and traitor have been found to influence jury evaluations of guilt for each of these criminal categories (Shoemaker, 1973).

Evidence does exist, then, to suggest that stereotypes operate as guiding imageries for action in the treatment of deviance. Applying Goffman's theoretical discussion of the stigma to the adjudication process, it may be observed that the stereotype becomes the "means for categorizing persons and the complement of attributes felt to be ordinary and natural for members of each of these categories," the product of which is to "allow us to deal with anticipated others without special attention or thought" (Goffman, 1963:2). A *legally* problematic situation would seem to be particularly prone to the use of such categorizations. Where constraints of time, personnel, and the sheer number of individuals who must be processed preclude full enforcement or extensive investigation, officials are likely to depend on shorthand methods in administrative decisions. Such methods include inspection of the offender and the offense for conformity to the popular conception of criminality.²

² Quinney (1970) is to be credited with the development of the notion of criminal stereotypes. In his own work, the stereotype is the medium through which powerful segments of

That many of the cues perceived by legal authorities are manifestations of class and race cultures has led a number of researchers to conclude that the legal system discriminates against these groups. It is possible to speculate, however, that more than class and race, cultural stereotypes of criminality determine the decisions of legal authorities. While these stereotypes include class- and race-related characteristics, they are not restricted to, nor do they include all members of these groups.

THE DATA

In order to examine this issue, a study of the legal treatment of individuals arrested on general charges of murder was conducted. The records maintained by a diagnostic and evaluation clinic attached to the court in a large urban jurisdiction in the northeastern United States and the indictment files secured from the Office of the Clerk of Courts provided the data used in the research.

Established in the mid-1930s, the court clinic has been charged with the diagnosis and evaluation of selected offenders as part of pre-sentence investigation. While most of its long-term efforts have involved the evaluation of sex offenders, in 1955 the clinic established a routine policy of examining cases of criminal homicide. Consequently, all persons arrested for murder in this jurisdiction are seen at the clinic, where an exhaustive study is done of their psychological condition and social background. If the findings indicate that the defendant is insane, the clinic notifies the court and proceedings are initiated for commitment to a mental hospital. Otherwise, the information is summarized and forwarded to the presiding judge for use in sentencing, in the event that the defendant is found or pleads guilty. If the defendant is found not guilty or if the case is dismissed, the sealed envelope is returned to the clinic unopened. In either event, upon its completion, the court notifies the clinic

of the specifics regarding the final disposition of the case.

In selecting the cases to be analyzed, an exhaustive list of all persons arrested on general charges of murder in the jurisdiction was compiled from the clinic files. Four hundred and forty-four cases, a 50 percent random sample, covering the period from January 1, 1955, through December 31, 1973, were selected for analysis.

The clinic records provided thorough and systematic data on the social characteristics of the defendant, any prior offense record, the circumstances of the offense and the results of the psychiatric evaluation. As regards the legal data, however, it was found that the information was not always contained in the clinic reports or that there were certain contradictions in the records concerning award of bail, the identity of the attorney or the results of post-sentence appeals. Because of these lacks, it became necessary to secure the latter data from the indictment records maintained by the Office of the Clerk of Courts. These records supplied information regarding the type of counsel (private, private appointed or public), bail decisions, the type of trial (jury or non-jury) and the final conviction awarded.³

While it is acknowledged that the records maintained by the clinic and court are for other than scientific purposes, it is precisely this information that is used by legal authorities in the determination of the career outcome of the defendant. The data collected for this research, therefore, comprise much of the same information as evaluated by legal representatives in their decision-making processes. The comprehensiveness of the records, the opportunity they present for verification of recorded fact, and their similarity to the kinds of in-

society insure a consistency of definition of criminality. Through the diffusion of the popular conception, individuals become aware of the social characteristics of offenders, the appropriate reaction to crime and the relevance of crime to the social system.

³ Since both clinic and indictment records contained a variety of sources of the same information concerning the defendant, victim and the circumstances of the offense, a multiple check of recorded facts was made possible. Where discrepancies occurred, those sources closest to the legal stage in question were utilized for documentation. Thus, for example, discrepant recordings of final disposition by the clinic and court would result in adoption of the court documents for verification of this fact.

formation utilized throughout the legal system constitute a data source that may provide a most acceptable basis for the study of adjudication patterns.

THE "NORMAL PRIMITIVE": A CRIMINAL CONCEPTION

Evidence of the role of the criminal stereotype in the legal processing of defendants emerged somewhat serendipitously in the early stages of data collection. In a review of the psychiatric portions of the clinic reports, a diagnostic category surfaced which seemed to reflect an official usage of such a stereotype—the "normal primitive." This category has become part of the standard diagnostic terminology of the staff of the clinic and constitutes a meaningful classification for the court. The characteristics of the "normal primitive" were provided by the clinic and the diagnosis warrants a detailed description here.

While treated as a diagnostic category, the designation "normal primitive" constitutes a *social* description of a group of people whose behavior, *within their own social setting*, is best described as normal. The "normal primitive" comes largely from the foreign-born and black populations. Their lives are characterized by impoverished economic conditions which, as with their behavior, may be described as "primitive." Occupational achievements center around unskilled, menial labor, and these careers are often sporadic. Educational levels are minimal and testing indicates borderline to low-average intelligence. While the children of the foreign-born do acclimate to a less "primitive" existence, the offspring of the black population seem unaffected by improved educational and social opportunities.

The personality characteristics of the "normal primitive" are childlike or juvenile, the behavior and attitude being similar to that of an eight- to twelve-year-old boy. At the same time, acceptance as a *man* by his group is very important. In this regard, the "normal primitive" is sensitive and takes offense to any question of his masculinity.

Interaction among such individuals often occurs in bars where arguments readily result in aggressive encounters. Compelled to fight any challenger of his masculinity or courage, the "normal primitive" protects himself by carrying a lethal weapon.

While sexual patterns among the foreign-born are relatively stable, promiscuity among the blacks provides additional

grounds for aggression. Sexual prowess is a reflection of the masculinity of males, but is denied to females. Thus, when infidelity occurs, "as it inevitably does," the humiliation perceived by the male will result in threats and physical abuse that may produce the death of any one, or all members, of the sex triangle.

In summary:

the primitive man is comfortable and without mental illness. He has little, if any, education and is of dull intelligence. His goals are sensual and immediate—satisfying his physical and sexual needs without inhibition, postponement or planning. There is little regard for the future—extending hardly beyond the filling of his stomach and the next payday or relief check. His loyalties and identifications are with a group that has little purpose in life, except surviving with a minimum of sweat and a maximum of pleasure. He has the ten-year-old boy's preoccupation with muscular prowess and "being a man." Unfortunately, he lacks the boy's external restraint and supervision so that he is more or less an intermittent community problem and responsibility. (clinic description)

The "normal primitive" classification represents a conception of criminality that combines both class and race characteristics. The imagery suggests a group of people whose style of life and innate attributes predispose them to violence. The tendency toward physical aggression over "trivial" issues, histories of family disorganization, and tenuous marital ties, combined with a perception by the offender that the violent response is appropriate and necessary, are manifestations of the volatile life style in which the "normal primitive" is said to exist.⁴

The importance of this diagnostic category lies in its expression of a more general conception of criminality as it operates in the judicial system. In that the clinic diagnosis is part of the *sealed* information forwarded to the presiding judge, it is only *following* conviction that it becomes rele-

⁴ The "normal primitive" criminal conception is remarkably similar to social scientific depictions of members of the subculture of violence (see, e.g., Pittman and Handy, 1944; Benay, 1966; Wolfgang and Ferracuti 1967). Elsewhere we have argued that the social scientific "discovery" of such a subculture may be testimony to the effectiveness with which the stereotype of violent criminality has been applied (see Swigert and Farrell, 1976).

vant information in the adjudication process. Evidence that individuals diagnosed as "normal primitive" receive differential treatment prior to sentencing would suggest, therefore, a more diffuse operation of the conception. Thus, an exploration of the effects of such a stereotype on the processing of defendants in the case of homicide becomes the empirical focus of this work.

DESIGN FOR ANALYSIS

Research on the question of differential legal treatment is characterized by a tradition of limited empirical focus. Concerned almost exclusively with an examination of specific stages in the legal system, studies have concentrated on *either* access to bail (Foote, 1959; Ares et al., 1963), the nature of counsel (Ehrmann, 1962; Sudnow, 1965; Blumberg, 1967; Siegel, 1968), jury selection (Robinson, 1950; Strodbeck et al., 1957; Erlanger, 1970) *or* final disposition (Johnson, 1941; Garfinkel, 1949; Bensing and Schroeder, 1960; Bullock, 1961; Vines and Jacob, 1963; Wolf, 1964; Forslund, 1969; Farrell, 1971; Chiricos et al., 1972; Burke and Turk, 1975). While intervening relationships involving the status characteristics of the victim (Johnson, 1941; Garfinkel, 1949), the severity of the offense (Bensing and Schroeder, 1960; Wolfgang, 1961; Farrell, 1971; Burke and Turk, 1975) and the extent of prior record (Green, 1961; Farrell, 1971) have been examined, still the empirical treatment of adjudication has been confined to the effects of a limited number of variables on single stages of the legal process.

Such an approach fails to acknowledge the processual nature of adjudication. Differential treatment occurring early in the judicial process may have consequences for final disposition. Thus, the relationships between social characteristics of defendants and disposition may not be direct but, rather, may operate through a number of other variables relevant to the adjudication process. Therefore, it is imperative that the sequence of events leading to the determination of guilt or innocence be incorporated into the study of treatment patterns.

The nature of the data utilized in criminological research has traditionally limited the kinds of investigations conducted. Many of the variables relevant to such studies involve nominal data. Statistical analyses, therefore, have relied upon various cross-tabular schemes. While developments in log-linear techniques (Goodman, 1972; 1973a; 1973b) have introduced the possibility of imposing causal order on nominal data, the usefulness of this method is somewhat restricted. With the addition of each new variable, the possibility of alternative causal interpretations increases exponentially.

It has recently been demonstrated (Knoke, 1975; Goodman, 1976), however, that regression analysis of dichotomous variables produces results comparable to those obtained through log-linear techniques. The argument is that multiple regression may be robust enough to overcome the violation of assumptions produced when a dependent variable is dichotomized. Thus, with the restriction that some degree of variance exists in the dependent variable, the use of regression analysis may be approached with confidence.

The highly structured nature of the judicial system lends itself to a systematic analysis of legal processing. The discrete ordering of events from assignments of counsel, bail decisions and selection of trial format to final adjudication constitutes a series of stages that allows the researcher to assert the causal sequence of events.

Capitalizing on the nature of the system, then, an effort is made to trace the paths of influence among certain social and legal variables and the final disposition of cases by the court. The path analytic technique is particularly suited for such an exploration. For, having established causal priority among a system of variables, paths of direct as well as indirect influence may be assessed.

The construction of complete recursive path diagrams was executed. Using multiple regression techniques, each stage of the model was fitted to all preceding variables. Paths failing to produce standardized coefficients of at least .100 were de-

leted, and the remaining coefficients were recalculated.⁵ The path and correlation coefficients generated by this analysis are presented in Table 1.

HOMICIDE AND THE CRIMINAL CONCEPTION:
AN EMPIRICAL MODEL OF LEGAL
PROCESSING

Prior Conviction Severity

The first stage of analysis involves the specification of the effects of the social characteristics of homicide defendants on the development of prior conviction records. The importance of a criminal record in the adjudication process has been noted by a number of researchers. The use of this concept, however, has been restricted to an observation of the presence or absence of prior offenses (Farrell, 1971; Burke and Turk, 1975) or, if severity of criminal record is considered, to a simple summation of the number of offenses, felonies or misdemeanors for which each defendant was found guilty (Bullock, 1961; Green, 1964; Chiricos et al., 1972).

Given the reported significance of the variable, a more sensitive indicant of the seriousness of prior convictions seems required. Toward that end, it was noted that state law establishes the maximum penalty allowable for each degree of felony and misdemeanor. Such penalties would appear to provide an adequate estimate of the seriousness of offenses as officially recognized in a particular jurisdiction. In the present research, therefore, a summation of the prescribed maximum penalties for offenses for which the defendant was found

guilty constituted a ratio measure of prior conviction severity.⁶

The coefficients calculated for the exploration of this variable are shown in column D of Table 1. The sex and occupational prestige⁷ of the defendant do contribute to the development of a prior record. Males and individuals of lower occupational status have more extensive criminal histories, blacks do not.

This latter finding has important implications for earlier explanations concerning the role of race in legal treatment. For, it has been argued that the more severe sentences accorded blacks may be accounted for by the greater extent of prior criminal involvement among black defendants (Green, 1961). Since prior offenses are considered in pre-sentence investigations, the severity of the sentence awarded offenders with extensive records is said to be a reflection of a judicial decision to penalize more severely those whose legal backgrounds indicate a history of recidivism. Thus, if blacks receive longer sentences for their offenses than do whites, it is because of their greater involvement in prior criminal behavior.

The present analysis, however, indicates that race is not directly associated with prior offense record, but operates only through its relationship with occupational prestige ($r = .352$). The usefulness of previous convictions in explanations of racial differences in the adjudication process is therefore not apparent.

The contribution of sex to prior offense severity is presumably in terms of the provision of access to the means for enacting criminal behavior. Social roles and expectations afford males greater exposure to illegal opportunities. The association of this variable with prior offense severity,

⁵ Coefficients for the abbreviated model were computed using a least-squares estimate (Boudon, 1968:199-235). This procedure utilizes the entire set of antecedent variables in the estimation of path coefficients, rather than deleting the nonsignificant variables from calculations. The adequacy of the abbreviated model was assessed in terms of its ability to reproduce the original correlation matrices. A one-tailed test of the null hypothesis that the original and reconstructed correlations did not differ significantly from zero was utilized. Where these correlations did differ significantly and where the reinstated path produced a coefficient of at least .100, path coefficients were recalculated. This procedure was iterated until all coefficients were adequately reproduced.

⁶ Thus, a defendant with a conviction for robbery (maximum penalty, 20 years) and one for bookmaking (maximum penalty, five years) would receive a prior offense severity score of 25. Penalties ranged from 0 to 20 years, with no prior convictions for first degree murder. Sentences of less than a year were scored in terms of the percentage of the year involved. Persons awarded a 90-day sentence, for example, would receive a severity score of .25.

⁷ Occupational prestige was measured in terms of Treiman's (forthcoming) classification system.

^b Coefficients before the variable was dropped from the equation are presented in parentheses throughout the table.

then, has little theoretical relevance to the exploration of legal treatment. Thus, only the path from occupational prestige to prior offense record is of major concern to this work. In this regard, it may be observed that individuals of lower occupational status accumulate more extensive criminal records.

The "normal primitive" classification, as used by the clinic, designates persons whose violent behavior is said to be normal within their own social setting. Applied largely to minority populations, the label is reflective of a cultural stereotype of criminality. Thus, serving as an empirical indicator of a more popular image of individuals who are thought to be prone to the spontaneous expression of violence, the "normal primitive" classification provides the foundations for an analysis of the effects of criminal conceptions on the legal process.

To assess the impact of this conception on legal treatment in the case of murder, defendants were classified according to the absence or presence of the "normal primitive" diagnosis in their clinical evaluations. All prior variables were then examined for their influence in the determination of the diagnosis. Column E of Table 1 shows that the race and occupational prestige of defendants do, in fact, contribute substantially to the designation "normal primitive." Here we note that blacks and individuals of lower occupational prestige are more likely to be designated "primitive" than are whites or higher status persons.

Such a pattern is not surprising, given the meaning of the concept as formulated by the clinic. For, as noted previously, this conception of crime is based on a number of class- and race-related characteristics. More specifically, the label connotes a predisposition to violence among the black and the poor. An imagery of personal and social disorganization within which these groups are evaluated is said to underlie their tendency toward greater levels of interpersonal aggression.

Access to Legal Resources

The social characteristics of defendants, the severity of their prior conviction re-

cords, and the designation "normal primitive" must now be assessed in terms of influence on the availability of private counsel, award of bail and trial by jury. Differential access to such resources may constitute a crucial link in the determination of adjudication patterns. The nature of the interrelationships at this stage of the analysis, therefore, provides important information for an understanding of legal treatment.

The right to counsel. The system of public defense was developed in order to guarantee the indigent defendant the right to qualified legal representation. Yet the differentials in resources available to private and public counsel (Ehrmann, 1962; Siegel, 1968; Deatherage, 1972), as well as the political milieu within which the latter must operate (Siegel, 1968), have brought into question the quality of defense provided by the public attorney. Of particular concern is the fact that the limitations inherent in appointed counsel seem to affect final disposition patterns in criminal cases (Ehrmann, 1962:21; Chiricos et al., 1972: 562-4). Given the apparent centrality of counsel in determining legal outcome, then, it is important to specify the factors that facilitate access to the privately retained defender.

Column F of Table 1 depicts the patterns associated with retention of a private attorney. The best predictor of such retention is the higher occupational prestige of the defendant. Since indigence is the basis for assignment of public defense, this relationship is expected.

In addition to financial ability, the severity of a defendant's prior conviction record has a small but independent effect. That is, individuals with extensive criminal records are more likely to be assigned public counsel. A suggested explanation of this phenomenon involves the decision of private counsel to refuse those cases where successful defense may be problematic. The presence of a criminal history resists the application of an imagery of innocence. When such a presumption cannot be sustained, a defender may be unwilling to risk the courtroom consequences. Protective of his reputation as a successful criminal lawyer and sensitive to his loss of bargain-

ing power with the prosecutor, the private attorney may withhold legal services from those defendants whose prior experiences with the law are seen as predictive of career criminality.

Of special interest is the association between the criminal conception of homicide and retention of a private attorney; the coefficient evident here, although in the right direction, approaches insignificance ($P=.096$). An explanation of this lack of relationship concerns the number of "normal primitives" who also come from lower occupational positions. Table 2 depicts a cross-tabulation of retention of private counsel and the "normal primitive" designation while controlling for occupational prestige (occupation has been dichotomized according to the mean). The findings indicate that the influence of the popular conception on type of attorney occurs through the financial inability of such persons to retain private counsel, rather than through any direct effect of conformity to the stereotype.

Award of bail. The institution of bail was developed in response to the problem of deterring the accused from fleeing adjudication, while assuring him the right to the presumption of innocence through release from incarceration before trial (Foote, 1959:43). Guided by this principle, bail is to be set in graduated amounts that motivate persons of all income levels to appear in court at the appointed time. Rather than using the financial ability of defendants, however, it has been argued that judges often rely upon the severity of the present offense, as well as the prior conviction record, to determine bail amounts (Foote, 1959). Since these factors are presumed to be associated more

often with lower income defendants, bail procedures may be said to have a strong class bias.

Evidence also suggests that the inability to obtain bail has significant effects on final disposition. Studies have shown that defendants jailed before trial were more often convicted than those charged with similar offenses who were able to finance their release (Foote, 1959:47; Los Angeles Law Review, 1961:627; Ares et al., 1963:83). Social class, therefore, through the operation of the institution of bail, may have important consequences for adjudication in criminal cases.

An additional word must be said about the nature of the present offense and the decision to set bail. As noted, offense severity is an important consideration in determining the eligibility of a defendant for pretrial release. Indictments often involve an implied statement concerning level of intent and premeditation. Thus, a charge of first degree murder is a more serious offense than a charge of involuntary manslaughter. In the present jurisdiction, however, individuals are arrested and indicted on a general charge of murder. The degree of the offense, along with the guilt or innocence of the defendant, is determined only at the time of the trial. Therefore, offense severity as it is specified in the formal charge, is automatically controlled in this study.⁸

⁸ Official criteria for determining bail eligibility include an assessment of the "nature of the offense and any mitigating or aggravating factors that may bear upon the likelihood of conviction and possible penalty" (Criminal Code Manual issued by the state in which this study was conducted). It is the determination of the effects of the criminal stereotype on evaluations of mitigating and aggravating factors, when the nature of

Table 2. Retention of Private Attorney by Normal Primitiveness Controlling for Occupational Prestige

$$\chi^2 = 6.203, df = 3, P < .20.$$

The results of an examination of the causal antecedents to award of bail in the case of homicide are shown in column G of Table 1. Occupational prestige was found to have little direct influence. Rather, this relationship occurs through the effects of prior offense record, the nature of counsel and application of the label "normal primitive."

That a defendant with an extensive prior conviction history is more likely to be detained before trial seems to be a consequence of two related factors. On the one hand, the withholding of bail or establishing its amount at excessive levels represents a court decision to detain the repeat offender. On the other hand, there may be operative the belief that individuals who have already been convicted of violating the law are more likely to be guilty of the present offense as well. The question of pretrial release in this case becomes inconsequential.

Another influence in the award of bail is the type of counsel. Privately retained attorneys are more successful in securing bail for their clients than are publically appointed attorneys. This relationship operates independently from the financial ability of the defendants involved.⁹ Thus, access to resources early in the legal process has consequences for the acquisition of additional resources at later stages.

Finally, individuals designated as "normal primitive" are also denied bail. This not only occurs through the nature of the legal services provided them as indigent defendants, but is also a direct effect of their status as "normal primitives." The denial of bail to those whose characteristics conform to a popular conception of the homicidal type suggests that a presumption of guilt is made by the court before official adjudication occurs.

Trial format. The final legal resource variable to be considered is that of trial format. The right to trial by jury is guaranteed all defendants who plead not guilty to the charges against them. Only those

who admit their guilt or who waive their right to trial are disposed of by a judge.

An empirical examination of the effects of the several variables discussed thus far on selection of trial format reveals that the only significant path of influence was that generated by the "normal primitive" designation (Table 1, column H).

It is interesting to note that there is no direct path of influence from attorney to trial format. It has been argued that negotiations between prosecutor and attorney will often result in a bargained settlement of the case (Newman, 1956; Alschuler, 1968; Cole, 1970). While all attorneys engage in plea negotiations, such negotiations are most often utilized by appointed counsel (Blumberg, 1967). The absence of a direct relationship between attorney and trial by jury, however, suggests that the origins of the negotiated plea lie outside the initiative of the participating attorneys. Rather, we note that the single most important determinant of type of trial is the "normal primitive" criminal conception.

Once again, we interpret this finding in terms of the impact of the stereotype of criminality on legal outcome. Recalling Sudnow's (1965) discussion of normal crimes, it may be suggested that the characteristics typically associated with homicide have a direct effect on the quality of treatment afforded individuals whose offenses are seen as normal. Thus, the appearance of a normal homicide, as one committed by an individual whose culture and characteristics are said to be associated with violent behavior, exerts an influence on trial format which is independent of the nature of counsel.

As with the effects of "normal primitiveness" on the award of bail, the implications of this relationship may be viewed within the context of a presumption of guilt. The denial of bail and the entry of a guilty plea before the court represent a definition of culpability, the criterion for which is conformity to the criminal stereotype. Once that evaluation is made, the legal resources essential for the successful defense of a criminal defendant are, in the eyes of legal representatives, superfluous. Without such advantages, equalitarian legal treatment itself becomes problematic. Public

the charge is held constant, that is the focus of concern in this stage of the analysis.

⁹ The validity of such a statement, of course, depends upon the adequacy of using occupational prestige as an indicator of financial resources.

defenders are not able to conduct a pre-trial investigation comparable to that initiated by private attorneys; denial of bail not only creates a definition of dangerousness and guilt, but often results in job termination—a factor weighed heavily by the court should probation become a sentencing alternative; and a plea of guilt removes the last vestige of the combative imagery upon which the legal system is founded.

Final Disposition

The last stage in the analysis involves an assessment of defendant characteristics, prior offense record, the "normal primitive" designation and access to legal resources as they affect final adjudication. The disposition of a case was measured in terms of the charge for which the defendant was found guilty.¹⁰ Since defendants originally charged with criminal homicide were sometimes convicted of crimes other than the two degrees of murder and two degrees of manslaughter, final conviction was scaled according to felony and misdemeanor levels. Thus, charges included first degree murder, first degree felony (second degree murder), second degree felony (voluntary manslaughter), first degree misdemeanor (involuntary manslaughter), acquittal, and dismissal (including *nolle prosequi* and demurer sustained). Column I of Table 1 displays the coefficients generated in the analysis.

The sex and occupational prestige of defendants are directly related to severity of final disposition. Males and persons of lower occupational status are convicted of the most serious charges.

¹⁰ Sentencing decisions are dependent upon the conviction awarded defendants. Within each offense category, however, the range of possible sentences is both limited and typically established by formula. Thus, cross-tabular analyses of sentences imposed within each degree of homicide reveal no significant differences. It appears, therefore, that discretionary treatment occurs earlier in the legal processing of criminal defendants. In addition, it is following conviction that the judge has access to the pre-sentence recommendations and diagnoses of the clinic. Since the focus of this research is to ascertain the effects of a shared conceptualization of the violent offender on treatment severity, it is necessary to examine those stages of adjudication that precede official access to diagnostic information.

That women are convicted of lesser offenses than their male counterparts is not surprising. Being female seems to be a mitigating factor in the assessment of criminality in general. It is only in regard to certain moral offenses, especially the sex codes, that women are accorded official recognition as law violators (see, for example, Sutherland and Cressey, 1974:126-9). A combination of a social "pedestal effect" as well as the definition that violent behavior is a male phenomenon contribute, we might speculate, to the less severe treatment accorded women accused of homicide.

Of particular theoretical interest is the direct effect of the defendant's occupational prestige on final adjudication. Individuals of lower status are found guilty of serious crimes more often than those of higher status. Thus, in addition to the advantages that it effects at earlier stages of the legal process, higher occupational prestige also produces a more favorable adjudication before the court.

A defendant's prior conviction record also appears to influence final disposition. Since a decision involving guilt or innocence officially is to be without reference to prior criminal involvement, this relationship is somewhat surprising. It appears, however, that such information enters into the adjudication process through more informal channels. Whether it be the unwillingness of prosecution and defense to consider seriously a reduction of charge for the repeat offender, the judge's awareness of the criminal history of a defendant as he weighs the evidence, or the use of prior record in the attempt to impeach the credibility of one who testifies in his own behalf, the defendant's criminal history becomes an influential factor in the severity of final conviction.

The award of bail and trial by jury are the legal resources which have the most direct effects on the severity of final disposition, while the nature of counsel acts through its influence on bail. The findings, in general, indicate that access to these resources produces the less severe final convictions awarded by the court. Given such a pattern, the antecedents to legal resource acquisition become most relevant. In addi-

tion to the operation of social class in the ability to retain private counsel, the two most active determinants of adjudication in the case of homicide are the prior offense record of the defendant and his conformity to an imagery of violent criminality. The completed path diagram generated by this analysis is found in Figure 1.

DISCUSSION

The racial background and social class of criminal defendants traditionally have been the most important factors considered in the study of adjudication. Such attributes, however, have failed to produce conclusive evidence regarding the quality of justice available in the United States. Rather, there appears to be a much more subtle motivation for the discretionary dispensation of justice—the criminal stereotype.

Occupational prestige did emerge as an important factor in the present empirical analysis. It must be noted, however, that the variable most affected by occupational status (that is, attorney) is, in fact, for sale. Little effort is made to disguise the importance of financial status in the ability to retain private counsel. Rather, judicial practices based on economic advantage have become institutionalized to the extent that the inherent inequities are not part of public consciousness. Thus, while the differential ability to purchase defense may elicit concern from those who seek full equality in the legal system, it certainly does not constitute the kind of invidious discrimination charged by the more vocal critics of criminal justice.

As for the relationship between social class and final disposition, we begin to approach the heart of the issue of differential legal treatment. Independent of the financial ability to retain a private attorney, higher social status merits a defendant a more lenient conviction. For an explanation of this pattern, we must look not to an overt attempt by the court to reward the wealthy and penalize the poor, but to the imagery that surrounds the adjudication of defendants. Thus, it may be suggested that the leniency of legal treatment of middle and upper class persons is inspired, in part, by the dominant motivations of punish-

ment and deterrence, (Farrell, 1971). The offender is to suffer not only in proportion to the severity of his crime, but so that he will weigh the advantages and disadvantages of a repeated offense.

For rich and poor alike, the decision to punish, therefore becomes a calculus of loss and pain. The lower class defendant, with minimal status in his community, little occupational prestige and a personal life most frequently described as disorganized, comes to the court with little to lose except freedom from incarceration. The higher status person, on the other hand, simply as a result of arrest is said to have suffered greatly. Suspended professional license, loss of status in the community, personal and familial trauma are seen as being sufficiently punitive and deterrent. Incarceration becomes superfluous when so much is said to have already been lost.

The applicability of this argument is reinforced by observations made within the context of occupational and corporate criminality. For example, while the Incredible Electrical Conspiracy involved losses far exceeding those accrued at the hands of the more conventional criminal, the highest penalty awarded a co-conspirator was 30 days (Smith, 1961a; 1961b). Convictions and sentences of the more recently adjudicated Watergate defendants were similarly proportioned. Popular sympathy generated over the loss of job and prestige incurred by those involved in these ventures testifies to the diffusiveness of the ideology of punishment, an ideology shared by laymen and professionals alike.

The distinction between overt discrimination and compliance with an institutionalized imagery is an important one. The credibility of the legal system, as well as that of judicial administrators, would be seriously threatened should evidence of the penalization of persons for reasons of class be substantiated. Legal safeguards of the rights of lower status persons would make accountable the authorities who flagrantly violate those rights. If, however, the decision to invoke negative sanction occurs within the rationale of a popular ideology of crime and punishment, the legal authority is free to act.

It is already a common practice to take

^aL-H is low to high,
F-M is female - male, and
B-W is black - white.

Figure 1. Final Charge by Legal Resources and Defendant Characteristics

into consideration the presence of a steady job and stable marital ties in the decision to probate or parole the conventional offender. The application of this same notion of "fair play" in the administration of justice to higher status persons is also an acceptable practice and does not generally invoke outrage or allegations of preferential treatment. Rather, in terms of the original logic, justice indeed has been done. The higher status offender, given a middle class measuring rod, has the most stable ties in the community, is a most productive person socially and, as a result of apprehension, has suffered a threat to that status. "Fair play" mandates that such a person be excused from further degradation.

This approach to an understanding of legal treatment is further substantiated by the effects of race on adjudication. In the present analysis, race did not exercise immediate influence on legal processing. The only theoretically significant effects of race concern its strong associations with social class and the criminal conception, "normal primitiveness."

Here again it may be argued that the exercise of overt discrimination against minority group members is effectively prevented by statutory proscription. When class and race alone are used to determine patterns of legal treatment, therefore, race only appears to operate through its relationship with social class. For reasons cited above, the black defendant is not adjudicated on the basis of skin color; rather, decisions are made in light of his membership in the lower class—a position that earns him the perceived need for a more severe penalty.

Such an explanation of the effects of social status point to the inadequacy of the use of the objective criteria of class and race in the assessment of treatment patterns. The decision to penalize is not likely to be made simply on the basis of skin pigmentation and annual income. The search for such relationships, consequently, may account for the contradictory findings reported in the literature. A more promising effort in this area might lie in an evaluation of the effects of criminal conceptions on legal treatment. It is these conceptions that may be the media through which so-

cial and demographic attributes are filtered in judicial decision-making processes.

The evidence generated in the present research would seem to substantiate this assumption. The "normal primitive," as a conceptualization of the typical homicide offender, has emerged as a most important factor influencing final outcome in the court. That certain groups in society are differentially penalized because of the mandates of this conception of criminality becomes valuable information in an analysis of treatment patterns.

Concerning the designation "normal primitive," both race and occupation explained a significant portion of defendants who were found within this category. Blacks and individuals of lower occupational status were more often designated "primitive" than were whites or higher status persons.

The primary effects of such a label appeared in the lack of availability of legal resources. Individuals who were said to conform to this imagery both were denied bail and did not have access to trial by jury. Thus, the presumption of guilt implied by the application of the label became amplified when the court decided that bail should be withheld or when a plea of guilt before the bench was encouraged. In addition, because of the strength of the relationship between occupational prestige and "normal primitiveness," such individuals also lacked the financial ability to retain a private attorney. These legal resources, in their turn, interacted in such a way as to produce the more severe convictions accorded those with public attorneys, no access to bail, and a non-jury trial format.¹¹

¹¹ Such an interpretation involves a departure from the simple evaluation of direct and indirect paths in the determination of causal influence, for both are a function of the original association between independent and dependent variables. The use of this approach, for example, would result in the conclusion that the relationship between race and final charge is a non-significant one. Direct and indirect paths of influence, in this case, can only explain a zero-order correlation of -.03.

It is argued here that a far more useful approach to the problem of causality involves a recognition of the importance of variable sequence. Thus, it is possible to envision a series of relationships

The criminal conception of homicide surfaces as a critical variable in the analysis of legal treatment. In addition to the financial inability of certain segments of the population to purchase legal advantages, persons also may be penalized because of their conformity to such an imagery. Those defendants whose personal or social characteristics suggest their participation in a culture where the violent response is said to be appropriate are denied the presumption of innocence constitutionally guaranteed to all. The processing of such persons, consequently, takes on a routine nature. For when guilt is presumed, little justification can be found for providing defendants with the combative tools essential for successful defense of their cases. The lack of legal resources that mediate between initial charge and final outcome is, in turn, instrumental in maintaining an imagery of guilt. Assignment of public counsel identifies the individual with that class of persons, the indigent, out of which the criminal stereotype is formulated; denial of bail defines the defendant as a potential danger to society; and waiver of trial by jury is self-admission of criminal involvement. Those defendants, therefore, whose access to private attorney, bail or jury trial is blocked, are further confirmed in the stereotype of the crime within which they were originally defined. The sequence of events, from designation as apparently criminal through lack of provision of legal resources for their defense, produces the outcome predicted by legal wisdom—official award of criminal conviction.

MARXIST CLASS CATEGORIES AND INCOME INEQUALITY *

ERIK OLIN WRIGHT

University of Wisconsin, Madison

LUCA PERRONE

*Università degli Studi della Calabria, Italy
Università Statale di Milano, Italy*

American Sociological Review 1977, Vol. 42 (February):32-55

Marxian class categories have been almost totally ignored in systematic quantitative studies of social stratification and income inequality. Occupational status or a similar variable is almost always used as the core criterion defining the individual's position in the system of stratification. This study provides a preliminary operationalization of the Marxian class categories for use in quantitative research. The three most important of these classes—workers, managers and employers—then are analyzed to see what interactions occur between class position and the usual variables used in predicting income (education, occupational status, age and job tenure) and between class and race-sex categories. It was found that there is a substantial interaction between class position and the income returns to education; within class categories, however, there are no differences between race and sex groups in the returns to education.

In the study of social stratification, there is a major disjuncture between theoretical traditions and quantitative empirical work. Of all the theoretical traditions in sociology, social inequality probably plays the most central role in the Marxist perspective. Yet, quantitative investigations of the

causes and consequences of inequality have almost totally ignored Marxian categories. Marxists have been suspicious of quantitative, multivariate approaches to the study of social reality, and the practitioners of multivariate statistics generally have viewed the Marxist perspective as offering little of interest for empirical research.

The present research is an attempt to bridge this gap between the Marxist theoretical perspective and the rapidly growing body of quantitative studies of social inequality. The first part of the paper will discuss briefly the logic of the Marxist concept of class and present a preliminary operationalization of the Marxist criteria for class position for use in quantitative research. We then will examine an empirical

* We would like to express our gratitude to Robert Quinn, Graham Staines, Linda Shepherd and others at the University of Michigan Survey Research Center for their assistance throughout this study. application of this operationalization in the study of income inequality.

THEORETICAL BACKGROUND

*The Marxist Concept of "Class"*¹

Few concepts in social science have been used in more diverse ways than "class." To some sociologists, class refers to categories of people occupying common positions within status hierarchies (Warner, 1960; Parsons, 1970:24; Williams, 1960:98). Others define classes as conflict groups determined by their position within authority or power structures (Dahrendorf, 1959:138; Lenski, 1966:95). Sociologists within the Weberian tradition see class as identifying groups of people with common economic "life chances" determined largely by market relations (Weber, 1968:927; Giddens, 1973; Parkin, 1971:18-23). In contrast to these usages, Marxists have defined class primarily in terms of common structural positions within the social organization of production (Bukharin, 1969:276; Lenin, 1969:486). In contemporary American society, this means defining class in terms of positions within capitalist social relations of production.

There are three important elements of this conception of class: classes constitute common *positions*, those positions are *relational* and those relations are rooted in the social organization of *production*. To say that classes constitute positions implies, to use Przeworski's (1976:3) apt expression, that there are "empty places" in the social structure which are filled by individuals. The analysis of class must be understood primarily as the analysis of such empty places, and only secondarily of the actual individuals who fill the slots. While questions of social mobility are important in a class analysis, there is a logical priority to understanding the empty places into which individuals are sorted (see Poulantzas, 1973:49-50; Marx, 1967:10).

Classes are not, however, just any "empty places" in social structure which

can be ordered in a hierarchical fashion. In the Marxist perspective, classes are not, as Barber (1957:73), would have it, "divisional units within systems of social stratification." Classes constitute common positions within social *relations* of production, and this means that classes must always be understood in terms of their relationship to other classes. Thus, the theoretical starting point of a class analysis is to decode the social relations of production within a particular society in order to uncover the class positions which they determine.

The traditional Marxist analysis of the class structure of capitalist society has centered on three criteria underlying social relations of production: (1) ownership of the means of production; (2) purchase of the labor power of others; (3) sale of one's own labor power.² These three criteria generate the three basic class categories of capitalist society: *capitalists* own their own means of production, purchase the labor power of others and do not sell their own labor power; *workers* do not own their own means of production and therefore cannot purchase the labor power of others, but do sell their own labor power to capitalists; and the *petty bourgeoisie* do not sell their own labor power, nor (except perhaps in a very limited way) purchase the labor power of others, but do own their own means of production. For many purposes, especially for the analysis of mid-nineteenth century capitalism, these were probably adequate criteria, at least as a first approximation; for the analysis of contemporary capitalism, they need some important extensions.

The present analysis will focus on only one of the possible extensions of this basic typology, the emergence of an authority structure within the capitalist enterprise which is *partially* differentiated from own-

¹ For a much more elaborate discussion of the Marxist concept of class, see Wright (1976a:20-90; 1976b).

² It might appear that sale of one's own labor power is equivalent to not owning the means of production and thus is a redundant criterion. However, in all class societies there are people who neither own the means of production nor sell their labor power—in precapitalist society, slaves; in capitalist society, students, many housewives and others who do not participate directly in production.

Table 1. Expanded Marxist Criteria for Class

	Criteria for Class Position			
	Ownership of the Means of Production	Purchase of the Labor Power of Others	Control of the Labor Power of Others	Sale of One's Own Labor Power
Capitalists	Yes	Yes	Yes	No
Managers	No	No	Yes	Yes
Workers	No	No	No	Yes
Petty Bourgeoisie	Yes	No	No	No

ership. This expanded typology is presented in Table 1. The traditional Marxist criterion of "employing labor power" really contains two distinct dimensions. First, being an employer gives the capitalist legal rights to the *product of labor*. Second, being an employer gives the capitalist control over the *activities of labor*, over the labor process. In nineteenth century capitalism, these two dimensions tended to be united in the entrepreneurial capitalist; today, especially in the large corporation, they tend to be partly differentiated.³ This

implies the emergence of a new social category, generally referred to as managers. Managers in this typology are wage-laborers who do not own their own means of production, do not formally employ workers, but who do control or supervise labor power. Thus they share some of the criteria of both workers and capitalists, which reflects the structural position of managers as a buffer between the capitalist class and working class.⁴ This enlarged typology will

³ Opponents of the Marxist view of class have argued that with the institutional separation of ownership and control in the modern corporation, property ownership has progressively declined as an important element in the structure of inequality and, thus, an analysis of capitalist social relations of production per se is unnecessary (see especially Bell, 1973; Berle and Means, 1932; Galbraith, 1967). Of course, no one can deny the considerable growth of managerial hierarchies in the modern corporation and the general decline of the family-owned firm in favor of the joint stock company (although, as Zeitlin (1974) argues, there are considerable data to indicate that proponents of the "managerial revolution" thesis have grossly exaggerated these changes). The issue is not whether or not professional managers play a bigger role in running corporations today than 100 years ago, but how such managerial positions should be structurally interpreted. Obviously, if property ownership is taken to be simply a juridical category defining formal legal title to the apparatus of production, then the emergence of managers at the top of large corporations signals the demise of property relations. But proponents of the class structure perspective increasingly have stressed that ownership must not be understood primarily in legalistic terms. Rather, ownership of the means of production constitutes a complex system of social relationships, of enforceable rights and claims to the apparatus of production (see especially, Balibar, 1970; Poulantzas, 1975; Bettelheim, 1973;

De Vroey, 1975). It is a sociological question, not a formal legal one, whether the appearance of a separation of ownership and control, in fact, may hide a new integration of the two. Understood in this way, the main significance of the rise of managerialism is not the abolition of property relations, nor the demise of the capitalist class but, rather, the reorganization of ownership structures from individual forms of capitalist ownership to more collective forms of ownership. The dominance of the capitalist class is no longer primarily mediated through personally manipulated individual businesses, but through collectively run and coordinated corporate empires (see Menshikov, 1969). Capitalist social relations of production have not been transcended; they have merely been transformed. The Marxist class structure perspective thus argues that relations of production—understood substantively, not formally—remain the core criteria for understanding class structure and class antagonism.

⁴ It is very important not to confuse this typology with Dahrendorf's (1959) conception of class as common position within authority hierarchies. Two points of contrast are especially important: in Table 1, "authority" represents only one dimension of class relations; whereas in Dahrendorf's analysis, authority becomes the sole criterion for class position. Second, in the present discussion, authority is defined specifically in terms of the social relations of production, not the social relations of any organization whatsoever. For Dahrendorf, authority relations within churches are as much the basis of class position as authority relations within industry. For a

provide the basic conceptual framework within which the present research will be conducted.

Several brief comments about the typology in Table 1 are necessary. First, to say that this is a structural typology in which a person is placed in a class category on the basis of the four criteria does not imply that there are no ambiguous cases. For example, should a worker who in his or her spare time is a small-scale, self-employed artisan be considered a petty bourgeois producer? It is partially an empirical question rather than a purely theoretical one how neatly and unambiguously individuals can be placed into the slots. The critical point is that such ambiguity takes shape and has theoretical meaning only in its relationship to the structural categories.

Second, and perhaps more seriously, there is a certain ambiguity in the criteria themselves quite apart from the possible ambiguities of placing individuals into particular slots. Two such ambiguities are particularly important. (1) There is an ambiguity in the boundary between the capitalist and petty bourgeois classes. As defined in Table 1, petty bourgeois employ no labor power. This is surely an overly stringent criterion; a small shopkeeper who employs one helper is not in a different class position from a small shopkeeper who employs no one. The criterion "employs labor power" thus does not provide a complete definition of the difference between capitalists and the petty bourgeoisie. (2) In a complementary way, there is a certain ambiguity in the boundary between the capitalist class and the managerial category. As defined in Table 1, the president of General Motors would be called a "manager" rather than a capitalist, in spite of the fact that most of his income comes from the direct appropriation of profits. Clearly, *formal* legal ownership of the means of production and formal legal status as the employer of labor power are not sufficient criteria to differentiate capitalists from managers. For present purposes, however,

we will ignore both of these ambiguities. The typology in Table 1 therefore should be regarded as a first approximation clearly in need of refinement rather than as a fully elaborated class typology.⁵

Third, to say that these are structural categories does not imply that they are completely homogeneous, without any significant internal differentiation. There are large, wealthy capitalists and small, local capitalists; top managers and foremen (the lowest level in the managerial hierarchy); highly educated, well-paid workers and marginal, poverty-stricken workers. It would be absurd to argue that class and class alone is the only important element defining an individual's place in the system of inequality. But again, the point is that these various forms of internal differentiation—of intra-class stratification—are to be understood theoretically in terms of their relationship to the more general structural class categories.

Finally, it is very important not to think of these class categories as occupational groupings. Class, as defined in Table 1, is a way of looking at social structure entirely different from occupation. The term "occupation" designates positions within the *technical* division of labor, i.e., an occupation represents a set of activities fulfilling certain technically defined functions. Class, on the other hand, designates positions within the *social* relations of production, i.e., it designates the social relationship between actors. Knowing that an individual is a carpenter, for example, tells you that within the technical division of

fuller discussion of the relationship of Dahrendorf's concept of class to a Marxist perspective, see Wright (1976a:ch. 1).

⁵ Many critics of the Marxist framework have argued that the fact of such ambiguities negates the value of a structural class model altogether. This is equivalent to saying that because the platypus has webbed feet and a bill, the concept of "mammal" is useless. The point is that ambiguities are ambiguities precisely because of their relationship to structurally defined categories. It is, of course, important for a structural theory to provide an understanding of the ambiguities rather than to ignore them, but there is no intrinsic incompatibility between a structural theory and structural ambiguities. For a more thorough discussion of ambiguities in the class structure, see the analysis of "contradictory locations within class relations" in Wright (1976b). See also Carchedi (1975a; 1975b).

Table 2. Occupational Distribution within Class Categories (Full-Time Participants in the Labor Force Only, 1969 Survey of Working Conditions)

Occupation	Class Categories ^a				
	Employers	Managers	Workers	Petty Bourgeoisie	Total
Professionals and Technicians	2.9%	20.2%	12.5%	11.8%	11.1%
Managers, Proprietors and Officials	72.1	17.1	1.7	41.2	14.5
Sales	2.9	4.5	5.6	2.0	4.9
Clerks	0.0	14.1	20.0	0.0	15.2
Craftsmen	6.7	21.8	14.5	9.8	16.0
Operatives	1.0	13.8	29.4	3.9	20.3
Laborers	1.0	0.8	4.5	2.0	2.8
Service Workers	1.9	6.1	10.4	2.0	7.7
Farmers	11.5	0.4	0.0	27.5	2.8
Farm Laborers	0.0	1.2	1.2	0.0	1.0

^a See Table 3 for operationalizations of class position in the 1969 Survey of Working Conditions.

labor he/she physically transforms lumber into buildings; but it tells you nothing about that individual's class position. A carpenter could easily be a worker, a petty bourgeois producer, a manager or even a small capitalist. The occupational distribution for the various class categories is given in Table 2.

Operationalization of the Class Categories

The data for the present study come from the 1969 "Survey of Working Conditions" and the 1973 "Quality of Employment Survey" conducted by the University of Michigan Survey Research Center.⁶ A number of questions from the 1969 survey enabled us to construct a class typology that was reasonably close to the Marxian typology.

1. "Most of the time on this job do you work for yourself or someone else?"
2. "If you are self-employed, are there any people who work for you and are paid by you?"
3. "Do you supervise anybody as part of your job?"

⁶ The 1969 survey consisted of a national random sample of 1,533 adults 16 years and older; the 1973 sample consisted of a national random sample of 1,496 adults. In both surveys, only individuals active in the labor force were included.

These three questions generate a total of five categories as illustrated in Table 3.⁷

⁷ Several comments about these categories are necessary:

Employers: We are calling this category "employers" rather than capitalists since most of the individuals in the sample who fall into this category are extremely small businessmen. Seventy-eight percent reported that they employed nine or fewer workers, and only eight percent said that they employed 50 or more.

Managers and Workers: In response to the question about having subordinates, a majority of elementary and secondary school teachers responded that they did supervise people on their jobs. This would formally place them in our manager category. However, with very few exceptions (such as teachers who hold administrative jobs as well as teach), teachers should be classified as workers, not managers, since they do not supervise labor power. Therefore, we have reclassified all teachers as workers regardless of their responses to the question about having subordinates.

Petty Bourgeoisie: A pure *rentier* capitalist—i.e., an owner of stocks and other assets who did not employ anyone directly—would fall into the petty bourgeoisie on the basis of the criteria in Table 3. In reality, such an individual should be classified within the capitalist class, since the role of managing the flow of capital represents part of the capitalist position within social relations of production. Since it is unlikely that many such individuals are included in the present sample, this misclassification makes little practical difference.

Ambiguous: This category does not have a clear meaning in the present study. Except for the special case of a self-employed consultant who su-

Table 3. Operationalization of the Marxist Class Typology (1969 Survey)

	Operationalized Criteria for Class Position				N	%
	Self-Employed	Have Employees	Have Subordinates on the Job	Employed		
1. Employers	Yes	Yes	Yes*	No	110	7.4%
2. Managers	No	No	Yes	Yes	561	37.4%
3. Workers	No	No	No	Yes	739	49.2%
4. Petty Bourgeoisie	Yes	No	No	No	65	4.3%
5. Ambiguous	Yes	No	Yes	No	27	1.8%

* Three individuals reported that they were employers but had no subordinates. These individuals were included in the employer category.

EMPIRICAL APPLICATION OF THE CLASS TYPOLOGY

General Hypotheses

The class categories discussed above will be used in an empirical study of income inequality. There will be three focuses to this investigation.

Comparison of the explanatory power of class and occupational status. Virtually all of the recent sociological work on income inequality has used occupational status, occupational prestige or some closely related metric of occupations as the key mediating variable between the individual's social background and education and the individual's income. We have posed the concept of class, defined in terms of capitalist social relations of production, as an alternative paradigm for understanding inequality. One way (by no means the only way) of comparing these paradigms is to estimate a series of income regression equations and then to examine the relative changes in explained variance when class and other variables are included and excluded in various combinations. The expectation is that class position will have at least as much an effect on an individual's income as will the individual's occupational status, and that this effect will not disappear when status is controlled for.

Examination of the different patterns of

pervises other people's employees, this category probably represents a response error. Since less than two percent of the sample falls into this category, we will exclude it from all subsequent analyses.

income determination between classes. If class position is a critical mediating variable between social background and income, then it would be expected that class position would affect the ways in which background characteristics get transformed into income. That is, we hypothesize not only that class position has an independent impact on income from occupational position, but also that it affects the extent to which background characteristics themselves can be "cashed in" for income. In particular, the expectation is that class position will have a strong influence on the extent to which education influences income.

More concretely, we predict: (a) that the returns to education will be much greater for managers than for workers and (b) that the income of employers will be higher than that of managers and workers at every level of education, but that the returns to education for employers will be less than for managers.

The reasoning behind the first hypothesis is as follows. For *both* workers and managers there should be some positive returns to education for a variety of reasons: educated labor costs something to produce and, thus, the income going to educated workers and managers generally will include an increment to cover those costs at least partially; educated labor tends generally to be in short supply relative to uneducated labor and, thus, market forces will tend to push up the incomes of both skilled workers and managers.

However, because of the specific posi-

tion of managers within the social relations of production, there are forces which tend to increase the returns to education among managers above the returns for workers. The argument has two steps. First, because of the problems of social control of managerial labor, managerial hierarchies will tend to be characterized by elaborate incentive structures. In particular, the income gradients associated with managerial career ladders will tend to be quite steep. This, in turn, will create steep income gradients associated with position within the managerial hierarchy. Second, among managers, there will tend to be a fairly close relationship between education and position within the managerial hierarchy. This association is the result of several factors. (1) Higher levels of the hierarchy require certain skills that are produced (or at least certified) within the educational system. (2) The educational system socializes people to the work norms demanded for different positions in the hierarchy. In particular, higher education develops habits appropriate for higher levels within the authority structure. (3) The educational system helps to legitimate the managerial hierarchy as a whole through the meritocratic ideology of rule by experts and, thus, there will be a tendency for people with lower credentials *not* to be promoted above people with higher credentials. As a result of this combination of steep income gradients and steep educational credential gradients tied to managerial position, we expect that managers will have particularly high income returns to education. This reasoning will be discussed in greater detail in the final section of this paper.

The second hypothesis is based on the view that the income of employers is fundamentally a consequence of the quantity of property (capital) controlled by the employer rather than the employer's education. Therefore, education should matter for the employer's income only if, *among employers*, there is a strong relationship between quantity of property and level of education.

It is very important to understand the logic of these comparisons of returns to education in different classes. We are not

touching directly on questions of social mobility, i.e., how people get sorted into class positions. What we are asking is: once a person gets into a class position, by whatever sorting process, does the class position itself have an impact on how much difference an individual's education is likely to make for the individual's income? We are therefore, in a sense, using regression equations to tap characteristics of the structure of class itself rather than to represent the status-attainment process at the individual level.⁸

Examination of the differences in patterns of income determination between blacks and whites and between men and women within classes. One of the main preoccupations in the stratification literature has been the analysis of differences in the status-attainment process among blacks and whites and, more recently, men and women. One of the most robust findings of this body of research is that blacks in general receive less income per increment in education than do whites (see Siegel, 1965; Duncan, 1969; Weiss, 1970).⁹ None of

⁸ This point may be somewhat clearer if we consider a more concrete example. Suppose we wished to compare the relation of education to wages in two businesses. In one business, education is irrelevant for pay; in the second business, pay scales are closely pegged to educational credentials. There are two empirical strategies that could be adopted for revealing this pattern: formal pay scales and job requirements in the business records of the two firms can be used to estimate the returns to education; or a survey of the personnel of the businesses and use of individual-level data to estimate the returns. In either case, the resulting regression equations should be seen as characterizing the firms rather than the individuals. This becomes most obvious in a situation in which education itself becomes an important criterion for an individual entering one or the other of the two businesses. In such a case, the regressions of income on education *within* each firm would tell very little about the total relationship of education to income for individuals. In our analysis, class categories are analogous to the firms, and the regression equations should be interpreted as reflecting characteristics of the class positions as such.

⁹ The work of Stolzenberg (1975) represents a partial exception to this general finding that the returns to education are lower for black males than for white males. Stolzenberg finds that within detailed occupational categories the *rate*

these studies, however, has controlled for class position defined in terms of social relations of production. If it is true that managers receive much higher returns to education than workers, as hypothesized above, and if it is true that blacks are more concentrated than whites in the working class, then it would be expected that much of the differential returns to education for blacks and whites might be due to the distribution of races across class categories. Therefore, we will compare the returns to education for blacks and whites *within class categories* in order to control for this class composition effect. We will do the same analysis for men and women.

Statistical Method

For the direct comparison of class and status the following standardized regression equation will be estimated:

$$\text{Income} = \beta_1 \text{ Education} + \beta_2 \text{ Age} + \beta_3 \text{ Status} + \beta_4 \text{ Employer Dummy} + \beta_5 \text{ Worker Dummy}$$

We will then examine how much the R^2 for the equation drops when the class dummy variables are excluded, when status is excluded and when both are excluded.

The analysis of the interaction patterns will involve a fairly straightforward application of the analysis of covariance. We will compare the various class categories and sex and race categories within classes in terms of a series of regression equations to see (a) if they differ significantly in the

slopes of the independent variables in the equations and (b) if a significant "gap" in income exists between the compared groups when the independent variables are controlled for. Figure 1 illustrates these two kinds of comparisons for the simple regression of income on education for managers and workers. The test for the significance of slope differences simply involves testing whether the slope of the manager minus worker regression is significantly different from zero.¹⁰ It is somewhat less obvious how to test the significance of the gap in income. The difficulty is that the magnitude of this gap is strictly dependent upon the level of education at which it is assessed. Thus, in Figure 1, if managers and workers were compared at zero education (the usual constant term in regression equations), the gap would be slightly negative; if they were compared at the workers' mean education (\bar{E}_w), the gap would be positive, but relatively small; if they were compared at the managers' mean education (\bar{E}_m), the gap would be positive and large. There is no standard convention as to which of these possibilities is the most appropriate. In the present analysis, we will assess the gap in income at the value of the independent variables halfway between the means for each of the two groups being compared. In Figure 1, this is indicated as $\frac{\bar{E}_w + \bar{E}_m}{2}$. The gap at this point represents

the expected difference in income between a worker and a manager with identical education equal to the average of the mean worker and mean manager education. We will refer to the comparison of expected incomes at this point as the analysis of the "average gap" in income between the groups being compared.

of income returns are fairly similar for the two races. However, Stolzenberg's results are not strictly comparable to those of the other studies cited above or the present research since he measures the *rate* of income returns to education rather than income returns as such. Stolzenberg uses a log transformation of the income variable in order to measure approximately the proportional increase in income for a unit increase in education rather than the absolute increase in income for a unit increase in education. It is quite consistent to find that blacks receive much lower absolute increases in income than whites per unit increase in education and yet that they receive equal (or even greater) proportional increases in income. Since at every level of education the income of blacks tends to be less than that of whites, a smaller absolute increase in income may produce an equivalent proportional increase.

¹⁰ This is accomplished by constructing a dummy variable for one of the nominal categories in the comparison and then estimating a regression equation with education, the dummy variable, and the dummy variable times education as independent variables. In such an equation, the dummy variable interaction term represents the difference in slopes for the two groups being compared. A direct t-test of this coefficient thus tests the significance of slope differences between the two groups (see Kmenta, 1971:419-23).

Figure 1. Illustration of the Method of Structural Comparisons

Since the average income gap is assessed at a different level of the independent variables in each comparison, it is not possible directly to compare average income gaps for different comparisons. In order to do this, it is necessary to assess the gap at the same point on all comparisons. We will therefore also calculate a "standardized income gap" by assessing the gap at the level of the independent variables of the most privileged category in our analysis—employers. (This is equivalent to the common technique of substituting the means from a privileged group into the equations for a disadvantaged group as discussed by Duncan, 1969.) In Tables 6A and 7A, where we report the basic regression equations for our analysis, this standardized income gap constitutes the difference in "adjusted constants" for the various groups.¹¹

¹¹ To conduct a t-test on these various gaps, it

Specification of Equations for the Analysis of Interaction Patterns

Every regression equation contains the answer to some question. The trick is for the equation which is estimated in fact to answer the question which is asked. Too often in sociological research any variable which is thought to be interesting is thrown into a regression equation without regard to its substantive relevance to the questions at hand.

There are two somewhat different questions which we would like to answer in the analysis of interaction patterns:

1. Do individuals in different classes, and in different race and sex categories within classes, differ in the amount of income they can expect to receive for *each additional increment* of education (comparison of slopes)?
2. Do individuals who are alike in all respects except that they differ in their class position, or who differ only in their race and sex while sharing a common class position, differ in the absolute amount of income which they can expect to receive (analysis of average income gap)?

These two questions pose somewhat different issues for the correct specification of the regression equations. For the first equation, ideally we would like to hold all factors constant which can be considered *causes* of education, but not those which are *consequences* of education. In particular, we would like to include a number of variables which describe the individual's social background and "intelligence." Unfortunately, no such data are available in the present survey. The result is that the estimated education coefficients in our analysis inevitably will be somewhat biased upwards.¹²

simply is necessary to shift the constant term in the dummy-variable interaction regressions to the desired value of the independent variables. A t-test on the constant term in such a regression then becomes a t-test of the income gap between the two groups being compared.

¹² The reason why it would be desirable to have such background variables in the equation

There is certainly no unanimity on the potential biases in education coefficients created by improperly measuring or by omitting social background variables. Bowles (1972), for one, argues that such biases are likely to be substantial. There is, however, considerable research on the effects of social background and education on income (Duncan, 1969; Blau and Duncan, 1967; Jencks et al., 1972) and of measured IQ on income (Jencks et al., 1972) which suggests that the bias in the education coefficient caused by the omission of the relevant background variables should not be terribly large. More importantly, even if these biases are not trivial, since our main interest centers on the *differences* between various groups rather than the absolute values of the regression coefficients, the problem of bias should become less critical. If we are willing to assume that the bias due to the omission of background variables is in the same direction for both groups, then the bias in the estimate of the difference in coefficients will necessarily be less than the most biased of the two individual coefficients and, generally, less than both. In the limiting case where two groups have identical biases, the estimate of the difference in coefficients actually will be unbiased.

Because of this absence of background variables, therefore, the core of the analysis of slopes will rest on comparisons of the simple regression of income on education for the various categories.

For the second question, we would like to hold constant all factors in addition to

education which have any significant impact on income. The list of such factors is, of course, very large and includes occupational status, on-the-job training, seniority, work experience, industrial sector, geographical location, migration, and so forth. For the present purposes, we will limit ourselves to three of these: job tenure, age (as a proxy for work experience) and occupational status.

We are including these additional equations not to provide more precise estimates of the education coefficient as such, but to see if the average gaps in income disappear as controls are added.¹³ Again, the income gap, as we are measuring it, represents the expected difference in incomes between two individuals, one from each group, that would occur if the two individuals had the same levels on all the independent variables equal to the averages of their respective group means. If this gap were entirely due to differences in the levels of education, occupational status, tenure and experience, then the gap should become negligible when these factors are all included in the equation.

While the actual value of the education coefficient in these expanded equations has little intrinsic interest, the magnitude of the difference between groups in the edu-

is *not* because they necessarily would tell us anything about how people get sorted into class positions, but because the class interactions could conceivably be artifacts of various unmeasured background characteristics of the individuals occupying given class positions. Thus, if managers have greater returns to education than workers, it might be because they have different motivations due to higher status backgrounds. What appears as an education slope difference between managers and workers would, in fact, turn out to be a slope difference between high status and low status backgrounds. In effect, therefore, when we compare education slopes we are comparing returns to education plus returns to all the unspecified causes of education which also influence income.

¹³ In certain respects, these expanded regression equations provide less meaningful estimates of the effects of changes in education per se on income than does the simple regression. In particular, the inclusion of occupational status introduces a substantial downward bias in the estimate of the education coefficient since it holds constant one of the basic mechanisms by which education influences income. The regression which contains occupational status as well as education provides an answer to a rather strange question: how much additional income could an individual expect to receive for an increase in education providing that this increased education did not lead to a change in occupation? The constraint of not changing occupation (or at least not changing occupational status) certainly reduces the amount of extra income per increment of education, i.e., it biases the education coefficient downward. Unless this equation appears as part of a system of recursive equations (as in path analysis), the inclusion of the occupational status variable in the equation clearly gives a less meaningful estimate of the effects of education per se on income than does the simple regression of income on education.

cation coefficient in these expanded equations may give some clue as to the possible mechanisms which produce the differences between classes observed in the comparisons of the simple regressions. In particular, if the inclusion of the occupational status variable wipes out any differences between classes in the slope of the education variable, it would suggest that the differences in slope in the simple regression might be substantially the result of the occupational composition of the different class categories. Thus, while the basic purpose for constructing these expanded equations is to examine the average income gap between groups, we will also look at the effect of including the additional variables on the differences in the education slopes.

Therefore, for each interaction comparison, we will estimate two equations:

1. the simple regression of income on education;
2. the regression of income on education, tenure, age and occupational status.

Variables

Class. Class is measured by the criteria in Table 3. Unfortunately, in the 1973 replication of the original 1969 survey of working conditions, the question about employing others was dropped from the questionnaire. This means that the employer category and category 5 in Table 3 were merged, making the 1973 data somewhat less reliable in comparisons between employers and other classes. We will therefore rely on the 1969 survey for the analysis of interaction patterns.

Occupational status. Status was measured using the standard Duncan SEI scores. However, in the 1969 survey, only decile values from the Duncan scale were coded rather than the full two-digit scale.¹⁴ In our direct comparisons of class and status, we will rely on the 1973 data in order to avoid any problems of attenuation which might result from using decile scores. By using the full status scale and a slightly less well-measured class variable in these comparisons, we are maximizing the relative explanatory power of status.

Since in the analysis of the interaction patterns we are less concerned with the coefficients of the status variable as such, we will use the 1969 data in order to have the most reliable measures of class position. In any event, the results for the direct comparisons of class and status using the 1969 data and for the interactions using the 1973 data are substantively the same as those reported below.

Annual income. Respondents were asked to indicate their total personal annual incomes before taxes as well as the amount and frequency of their paychecks. If they failed to answer the annual income question, annual income was estimated from the response to the paycheck question. Annual *income* is being used rather than simply annual *earnings* since, for comparisons between classes (especially between employers and other classes), the exclusion of unearned property income obviously would understate real class differences. Total income therefore should be seen sociologically as an indicator of total economic rewards regardless of economic source.

Education. Education is measured by a quasi-credential scale rather than by years of education in the following manner:

- 0=elementary school or less
- 1=completed elementary school
(grade 8)
- 2=some high school
- 3=high school completed
- 4=some college

¹⁴ The decile status scale used in the survey is related to the full two-digit scale as follows:

Decile	Full Scale
0	01-06
1	07-13
2	14
3	15-18*
4	19-21
5	22-31*
6	32-39*
7	40-51*
8	51-65*
9	66 and over

* The decile split in these cases occurred in the middle of a category. In these situations, cases were randomly assigned above and below the 10 percent cut-off point.

5=college degree
6=post-college.

Each step on this scale represents a socially-recognized level of education. Although in practice it is highly unlikely that any of our results would have been different if years of education had been used instead of this scale, we felt that in an analysis of income determination a "credential" is a more appropriate unit of education than a year.

Job tenure and age. The job tenure variable is a simple measure of the number of years worked on the current job. Unfortunately, no question was asked on the survey about general work experience beyond tenure in current job. While realizing that there are some problems with age as a variable in an analysis of income determination, age will be used as a loose proxy for general work experience.

The Sample Used in the Analysis

For the purposes of the present research, we have restricted the analysis to those respondents who work full time, defined as 35 hours a week or more. While this reduced the sample size somewhat, especially for women, we felt that the analysis would be more straightforward if we avoided the special problems of analyzing the market for part-time labor.

In the analysis of interaction patterns, the sample also will be limited to workers, managers and employers, the three most important classes in advanced capitalist societies. In many respects, the petty bourgeoisie represents a remnant from an earlier era of capitalist development and, as a class, certainly is progressively becoming less important. While this class may be of considerable interest for certain problems; we will simplify the present study by excluding it from the analysis.

Finally, farmers and farm laborers (less than 4% of the total sample) are being excluded because of the difficulties of assessing income in kind for agricultural occupations. All of the results reported below remain virtually unchanged if farmers and farm laborers are included in the analysis.

RESULTS

Direct Comparison of Occupational Status and Class Position

Table 4 presents the regressions used to assess the relative contributions of occupational status and class to the explained variance in income. Table 5 presents the corresponding correlation matrix. In order to make these results as comparable as possible to the existing research on income determination and status attainment, we have restricted the sample to white males, nonfarm full-time participants in the labor force.

Education and age account for just over 15% of the variance in income. The additional increment in R^2 resulting from adding occupational status to this equation is only 4.1%, whereas the increment from the two class dummies is 9.4%. All of the variables taken together explain just under 27% of the variance in income among white males. Looked at in a slightly different way, when class is added to the equation containing status, the R^2 increases by 7.6%, whereas when status is added to the equation containing class, the increase is only 2.3%. Status and class alone each explain just over 14% of the variance in income. These results are highly suggestive that an extremely simple version of the Marxian class typology is at least as potent a variable in predicting income as the full Duncan socioeconomic scale.

Class Comparisons

Figure 2 and Table 6 present the results of the comparison of the various class categories for the simple regressions of income on education. Table 7 presents the results for the expanded regressions. Table 8 presents the mean values and standard deviations of the variables for all the class-race-sex categories being compared.

The results shown in these tables and figures strongly support the view that class has a substantial effect on the relationship of education to income. The results can be summarized as follows.

Workers versus employers and managers. The education slope for workers

Table 4. Comparison of the Explanatory Power of Occupational Status and Class (1973 Survey, White Male, Nonfarm, Full-Time Participants in the Labor Force Only)

4-3	Status Net of Education and Age					.041
5-3	Class Net of Education and Age					.094
1-5	Status Net of Education, Age and Class					.023
1-4	Class Net of Education, Age and Status					.076

was significantly flatter than for managers or for employers, and the overall level of the regression line was considerably lower in the simple regression equations (Table 6A:2-3; Figure 2A). Workers received, on the average, \$1,119 less for each increment in education than managers and \$3,413 less than employers. The average income gap between workers and managers was \$2,529 and between workers and employers, \$6,865. All of these differences were significant at the .001 level.

The addition of job tenure, age and occupational status into the equations did not eliminate the average gap in income between workers and managers or employers (Table 7B:2-3); i.e., most of the gap between the regression lines in Figure 2A cannot be attributed to the age-tenure-occupational status composition of the class categories.

Not only do the age, tenure and occupational status variables fail to close the

income gap between classes, they fail to eliminate the differences in the slopes of the education variable. Even when the control variables are added, workers still receive some \$2,563 less income per increment of education than employers, and \$870 less than managers. Furthermore, workers also receive much less additional income for increments in decile occupational prestige than either employers or managers; workers receive over \$2,000 less for each decile of prestige than employers and \$400 less for each decile than managers. These results further support the notion that the differences between classes cannot be considered simply artifacts of the mix of occupations in the different classes for if that were the case, the classes would not be expected to differ in the slopes of the occupational status variable itself.

Managers versus employers. The income gap between managers and employers was substantial in the simple regression equa-

tion (\$5,081) and was only partially reduced by the addition of the control variables. Contrary to our expectations, however, the slope on the education variable was significantly flatter for managers than employers in both regression equations. Some possible interpretations of this result will be discussed in the final section of this paper.

Class comparison within the white male category. By and large, the same results are obtained for white males examined separately as for the entire sample. The education coefficients are significantly lower for white male workers than for white male managers or employers in the simple regression and in the expanded regression. The income gaps were also substantial and statistically significant (Table 6B:5-6 and Table 7B:5-6). Thus, these class differences cannot be considered artifacts of the race-sex composition of the class categories.

In the comparison of white male managers and employers, the income gap is also significant in both equations, and the education slope for managers is significantly flatter in the simple regression (Ta-

bles 6B:4 and 7B:4). In the expanded regression, the absolute magnitude of the difference in education slopes between white male managers and employers is essentially as large as for all managers and employers (\$1,640 compared to \$1,693), although the *t*-ratio of the difference drops just below the 5% significance level. The unexpected result of employers having greater returns to education than managers thus occurs among white males as well as in the entire sample. Again, these class interactions cannot be considered a consequence of the race and sex composition of the class categories.

Class comparisons within the black male and white female categories. Although the direction of the income gap and the differences in the education slopes between managers and workers within the black male and white female categories are the same as within the white male category, the magnitude of the differences tends to be smaller. Among white females the education slopes of workers and managers were not significantly different for either of the regressions and, while there was a significant income gap in the simple regression, this gap was

Table 9. Class-Race-Sex Distributions (Full-Time Participants in the Labor Force Only, 1969 Survey)

Distribution of Classes within Race-Sex Categories

almost eliminated with the addition of the control variables (Tables 6B:7 and 7B:7). Among black males, the education slopes were marginally significantly different in both regressions, but the average gap in income was not significant in either regression.

Race and Sex Comparisons within Class Categories

Before examining the differences between race and sex categories within classes, it is important to stress that some of the most significant race and sex effects undoubtedly operate through mechanisms which sort people into the various class categories in the first place. Both women and blacks are underrepresented in the employer category, and women are underrepresented in the manager category as well (see Table 9). Furthermore, the present study is limited to full-time participants in the labor force. It has been shown that, even when educational and skill levels are controlled for, blacks have considerably higher levels of involuntary unemployment than whites (Harrison, 1972). It hardly needs to be added that sexism has acted as a powerful force for keeping women out of the labor force entirely or restricting them to part-time work. When we examine the differences between sex and race categories

among workers and among managers, it should be kept in mind that these are differences which occur after the effects of racism and sexism have operated to keep some people out of the labor force altogether, to prevent others from finding stable full-time employment, and to influence the race and sex distribution among classes of those people who are full-time participants in the labor force.

Race and sex comparisons within the manager class. Black and white male managers do not differ significantly in the slopes of any variables in either the simple or the expanded regressions (Tables 6B:9; 7B:9). It can reasonably be said that an increment of education has essentially the same payoff for blacks and whites, *once they become managers*.

There is greater ambiguity, however, in the analysis of income gaps. While in formal statistical terms, the average income gap between black and white male managers is not statistically different at the 5% level in either the simple or the expanded regression, the absolute magnitudes of the gaps are still large when compared to many of the other comparisons we are making. These results reflect the intrinsic ambiguity of using "significance level" as the criterion of the relative strength of the difference between groups. A low level of significance

of a difference in coefficients can mean either that the two groups really do not differ in the coefficient or that they do differ substantially, but the difference is measured very imprecisely (i.e., the test is of low power).

The comparison of sexes within the managerial class is less problematic (Tables 6B: 10-11; 7B: 10-11). Again, there are no significant differences in the slopes of any of the variables, with the exception of the education slope in the expanded regression in the comparison of white female and black male managers. We have no explanation for this result. However, there is a very substantial average gap in income between white female managers and both white and black male managers in both regression equations. With a large sample, even if it should turn out that there was a significant income gap between black and white male managers, these data strongly indicate that the sex differences among managers are considerably greater than the race differences.

Race and sex comparisons within the working class. By and large, the results for the comparisons of sex and race categories among workers are substantially the same as among managers. None of the race-sex categories differ in education slope in the simple regression and, with the marginal exception of the comparison of black and white women, none differ in the expanded regression (Tables 6B: 12-15; 7B: 12-15). Therefore, it appears that the returns to education are roughly the same for all workers regardless of race and sex.

Furthermore, *within* sex categories, there are also no significant income gaps between blacks and whites. Therefore, as in the managerial category, we cannot reject the null hypothesis that black and white male workers have essentially the same regression equations, and black and white female workers have essentially the same regression equations, especially for the simple regressions of income on education.

Between male and female workers of both races, however, there is a very significant average gap in income. The gap between white female and white male workers is some \$3,300 and between black

male and white female workers, over \$2,600 in the simple regressions. Adding the control variables has virtually no effect on these differences. Thus again, as in the managerial category, the sex differences within the working class are much more striking than the race differences.

GENERALIZATIONS AND INTERPRETATIONS

At the most general level, the results of this study clearly show that classes defined in terms of social relations of production are consequential in American society. The differences between classes in levels of income and in the relationship between education and income are substantial, and these differences do not disappear when we control for variables such as occupational status, age, job tenure, sex or race. Furthermore, in terms of explained variance in income, class position is at least as powerful an explanatory variable as occupational status.¹⁵ A number of other more specific generalizations can be made.

The returns to education within the managerial category are greater than within the working class category. This result was strongly supported both for the sample as a whole and for white males taken separately in both regression equations.

This is one of the most important findings of the study and has considerable implications for the understanding of income inequality. While much more research is necessary to decipher fully this class interaction in returns to education, we can offer some preliminary lines of interpretation. As suggested earlier, we argue that the higher returns to education among managers than among workers reflect the steep income gradients associated with mana-

¹⁵ It must be recognized that class itself still explains only a relatively small proportion of the total variance in income (14.5 percent in Table 4). A full model explaining income variation would have to include many other variables, such as economic sector, region of country, unionization, etc. The critical argument of this paper is not that class explains everything but, rather, that other variables must be examined in terms of their interactions with class position in order to unravel the nature of income determination.

gerial hierarchies on the one hand, and the role of education in sorting people into different levels of the hierarchy on the other.

In both Marxist and non-Marxist traditions, "wages" (and, correspondingly, income from wages and salaries) have been conceptualized as part of an exchange relationship—an unequal, asymmetrical exchange in the Marxist perspective which hides an exploitive relation; an equal, reciprocal exchange in non-Marxist perspectives which reflects the marginal productivity of the wage earner.

An alternative view is that wages are not merely payment for services rendered (i.e., exchange), but are also part of a *structure of social control* within businesses and bureaucracies. Wage differentials should be considered, in part, a political response to the problem of social order within organizations rather than either simply an economic response to the human capital of the wage earner or merely the phenomenal form of a system of surplus value extraction.

The conformity of the individual to the norms of any institution is guaranteed by a variety of threats of punishment for deviance and promises of rewards for compliance. The balance between these punishments and inducements; and their specific forms, depends strongly upon the individual's position in the process of production. For workers in the lowest skill levels, especially when they are in peripheral businesses, the dominant mode of control is threats of various sorts, especially the threat of being fired. For workers with higher levels of skills, particularly when they are employed in core industries, there is much more reliance on various positive inducements: progressively increasing pay and vacation time, good pensions, job promotions, and so on (Stone, 1974). For employees who occupy positions in the authority structure of an enterprise, the inducement mode of control is even more dominant. Repressive forms of control (such as the threat of being fired) become residual instruments used only in the last resort.

The dominance of rewards as the basic

mode of control of managers reflects a basic asymmetry of punishments and inducements as mechanisms of social control: punishments are administered only when concrete infractions are committed and discovered. They are, therefore, generally effective only for preventing bad behavior. Punishments are not a very effective strategy for encouraging responsible behavior. Rewards, on the other hand, can be doled out roughly in proportion to the quality of the individual's performance and thus can be used as a more flexible instrument for encouraging enthusiastic, responsible and even innovative behavior. In the case of workers at the bottom, there is little need for them to perform in a responsible and creative way. As with the private in the army, the employer is mainly concerned that the production line worker more or less does what he/she is told to do. Obedience rather than initiative is the basic performance norm. But for supervisors in general, and supervisors at the middle and top levels of the management hierarchy in particular, the interests of the organization require more than dependability and mechanical obedience. For the power of managers to be wielded effectively, their behavior must be controlled by mechanisms which encourage responsibility rather than simply repress deviance from the rules. It is therefore expected that authority hierarchies will be characterized by very steep income gradients.¹⁰

It might well be asked, what has this to do with the relationship of income to *education* in the manager category and the worker class? In addition to developing various skills, education can be seen as

¹⁰ It should be noted that this interpretation of the authority hierarchy income gradient is quite different from the logic of the Davis-Moore (1945) interpretation. We are not arguing that there is any inherent scarcity of talent or any inherent problems of recruiting people for positions in the authority hierarchy, but rather that once a person is in such a position, there is a problem of social control which is, in part, solved by the structure of income rewards. For a somewhat different elaboration of this perspective which emphasizes the punishment aspect of the control apparatus rather than inducement (see Wright, 1973:314-20).

having two complementary functions with respect to authority structures (Edwards, 1972; Bowles and Gintis, 1975). First, education serves as a legitimation for inequalities of power and second, education helps to socialize people to the different work habits, patterns of discipline and social demands of different positions in the production process. In particular, higher levels of education tend to socialize people to the work habits appropriate for occupying positions in the authority hierarchy. Among managers, it would be expected that there would be a fairly close association between their position in the authority hierarchy and their level of schooling. This association has been demonstrated by Tannenbaum et al. (1974:110-3). On the basis of the logic of social control elaborated above, we would also expect that there should be a fairly close association between income and the authority hierarchy (see Tannenbaum et al., 1974:106-8). Thus, we would predict that among managers there should be a fairly steep income gradient for educational attainment as well. This is precisely the result we have observed.

In these terms, the education coefficient for workers in Figure 2A can be thought of as the payoff to education for those people with zero authority, while the difference between the worker and manager regressions at each level of education reflects the extra income managers can get by cashing in their education on positions in the managerial hierarchy. If this interpretation of the steeper managerial returns to education is correct, then it would be predicted that, within specific levels of managerial hierarchies, the returns to education should be much closer to those of workers. Unfortunately, in the present study there are no data appropriate for testing this proposition.

The class differences between managers and workers tend to be less marked among white women and black men than among white men. White female managers and workers differ hardly at all in returns to education, and the average gap in their income is very small in both regression equations. Although there is a significant

difference in education slopes between managers and workers among black men, the income gap is quite small.

These results suggest that black male and white female managers look more like workers than do their white male counterparts. One partial explanation for this might be that black male and white female managers are more highly concentrated at the very bottom of managerial hierarchies than are white male managers. It would be expected that they would tend to be line supervisors of various sorts rather than middle managers, and that very few indeed would become top level managers in either private businesses or public bureaucracies. This would tend to depress the overall payoff for becoming a manager and reduce the differences between managers and workers. The present survey provides no data directly relevant to this hypothesis, and we have been unable to find other studies which systematically analyze the position of blacks and women in comparison with white males in authority hierarchies.

Even when education, occupational status, age and job tenure are controlled for, employers have greater income than either managers or workers. This result occurs in spite of the fact that the employers in the sample overwhelmingly are small businessmen rather than large capitalists (see footnote 7). Thus, despite theories of the managerial revolution, the postindustrial society and other perspectives which claim that authority and/or knowledge stratification has superseded property stratification, the results of the present research indicate that the class division between property-holders and non-property-holders is still very real, even when only small property-holders are considered.

The returns to education for small employers are much greater than for workers and managers. This was an unexpected result. Since employers are not paid a direct return to education but, rather, pay themselves an income out of their profits, the income of employers should be linked to education only to the extent that the quantity and profitability of their property was

closely associated with the level of their education. We did not expect this to be the case but, apparently, at least for small businessmen, such a link is present.

In retrospect, this is not so terribly surprising. Among quite small employers, after all, differences in education would correspond to differences between shopkeepers on the one hand and doctors, lawyers and other professionals on the other. Since 78% of the employers in the present sample employ fewer than ten employees, it seems likely that the relationship of education to type of business may account for much of the steepness of the employer education coefficient. Among larger employers, it would be expected that education would make less difference in income.

There is some suggestive evidence in the present survey which supports this interpretation. Eighteen employers in the sample stated that they employed ten or more employees. When the regression equations are run separately for this subgroup, it is found that indeed they do have much flatter education coefficients than employers who employed fewer than ten employees. In the simple regression, small employers received \$4,285 for each increment in education whereas the larger employers received only \$1,221.¹⁷ This coefficient is smaller than the one for managers. The average income gap between large and small employers, as one would expect, was relatively large—\$4,155. Because of the small number of large employers, it was not possible to test formally the significance levels of these comparisons. However, they do suggest that as the actual labor of an employer becomes a smaller proportion of the total labor of a business,

the education of the employer matters less as a determinant of his income. It would be expected that for truly large capitalists (employing 500 or more workers) the returns to education would be even smaller and the adjusted constants correspondingly higher.

The class differences between workers and employers are considerably greater than the differences between men and women or between blacks and whites within the working class. The standardized income gap between workers and employers is generally two to three times as great as the standardized gap between male and female workers of either race, and the gap between black and white workers of the same sex is, at most, a tenth as large as the gap between workers and employers.¹⁸ The differences in education slopes are very small between sexes or races within the working class, but are quite substantial and highly significant between workers and employers. Furthermore, race and sex groups within the working class differ by a maximum of about \$200 in returns for a decile increase in occupational status, whereas employers and workers differ by over \$2,000. In a Marxist perspective, these results are very much what would be expected. *In economic terms*, class exploitation is a theoretically more fundamental division within capitalist society than is either sex or race, and thus the differences between the working class and the capitalist class should be more substantial than the differences between male and female workers or black and white workers.

Within class categories, races and sexes appear to have very similar returns to education. These results must be considered somewhat tentative since the sample size, especially for the race comparisons, is relatively small. Nevertheless, it seems fairly safe to conclude that at least part of the

¹⁷ There was one outlier in the large employer group—an individual who employed more than ten workers but reported an annual income of only \$3,000. This individual also happened to have a low level of education, and leaving him in the regression increased the education slope for large employers considerably (to \$2,100 from \$1,221.) Since it is implausible that an employer of more than ten people would actually have a real income of only \$3,000 a year (presumably in this case the employer had a bad year and lived off his capital), we have excluded this individual from the regression.

¹⁸ Note that we are comparing "standardized income gaps" rather than "average income gaps" in this conclusion. It is impossible to compare average income gaps since they are assessed at a different point for each comparison. The standardized income gaps, on the other hand, are assessed at the same point, mean values of the independent variables for the employer category.

differential returns to education for blacks and whites is a consequence of the class composition of the two races. If this result is confirmed with more extensive data, it would suggest that racial discrimination operates more in sorting people into class positions in the first place than in giving them lower income for given levels of education and skills once they are in a class position.

Within class categories, the income gap between races tends to be much smaller than between sexes. The standardized income gap between white males and white females is nearly five times greater than between black males and white males in both the working class and the managerial category in the simple regression. The difference is even greater in the expanded regressions. Again, racism may be particularly important in allocating people into different class categories in the first place. However, once a person is located in a class position, sex differences in income are considerably larger than race differences.

Obviously, this study is only a first step in the development of a sophisticated use of structural class categories in quantitative research. It would be desirable in the future to use these categories in more elaborate path models of income determination including extensive information on background. It is also crucially important to examine the extent to which various class boundaries are crossed in the course of individual work-lives. While much research has been done on the movement across the blue-collar/white collar occupational "boundary," both within generations and between generations, none we have found systematically has explored the movement across structural class boundaries. The many questions concerning the internal stratification within structural classes also need to be researched. It is our hope that the present work will open up the possibility of bringing Marxist categories into the heart of quantitative research on social inequality as well as making quantitative research seem more relevant to Marxist social scientists. To ignore these theoretical and empirical issues is to ignore a crucial

dimension in the structure of inequality in American society.

STRUCTURAL AND EXCHANGE COMPONENTS OF VERTICAL MOBILITY *

McKEE J. McCLENDON

The University of Akron

American Sociological Review 1977, Vol. 42 (February):56-74

This paper focuses on the measurement of structural and exchange components of vertical mobility, with primary emphasis on occupational status mobility. The shortcomings of the study of vertical mobility are discussed. Then, assuming the use of interval scales, absolute, exchange and structural mobility are defined and measured at the individual level. Aggregate measures of each mobility component are also presented which can be computed easily from the means, standard deviations and correlation of the origin and destination distributions. Finally, the aggregate measures are applied to occupational status mobility data for 1962 and 1972-1974. Interperiod comparisons are discussed, as well as racial comparisons and sex comparisons. Educational mobility is briefly compared to status mobility.

Students of social stratification have long been interested in intergenerational occupational mobility because of its relevance to the subject of equality of opportunity or the "openness" of society (Sørensen, 1975a; Coxon and Jones, 1975). For this reason, they have been concerned primarily with vertical mobility, as opposed to horizontal mobility, and with exchange or pure mobility, as opposed to structural mobility. However, it will be argued in this paper that due to methodological problems and a lack of conceptual clarity, efforts to empirically separate vertical mobility into its exchange and structural components have been largely unsuccessful.

This paper represents an attempt to define and develop measures of exchange and structural vertical mobility. Absolute, exchange and structural mobility first will be defined and measured at the individual level. Measures of aggregate population mobility then will be developed from the individual level measures. And finally, these aggregate measures will be applied to recent data for the United States to assess interperiod changes and intergroup differences in mobility. No effort will be made

to explain individual differences in mobility or occupational achievement.

The definitions and measures of vertical mobility proposed in this paper are based upon three premises about the current state of thought and research on mobility. First, occupational mobility tables are inappropriate for the study of vertical mobility. Second, although status attainment models are more suited to the study of vertical mobility than are mobility tables, status attainment models do not directly address the subject of mobility and have, in fact, diverted attention away from improving the measurement of mobility. And third, the conceptualization of mobility has been less than adequate, particularly with respect to the task of measuring vertical mobility and its exchange and structural components. These premises will be elaborated upon further, but first it will be necessary to briefly review the distinction between exchange and structural mobility as well as previous efforts to measure the two.

Intergenerational mobility is most frequently studied through the use of an occupational mobility table consisting of the joint distribution of current occupation and father's occupation for a sample of the work force. The relevance of such a table for assessing the openness of society is complicated by the fact that the current occupational distribution of members of the

* I would like to thank David L. Featherman and Robert M. Hauser for their comments on an earlier draft of this paper. The comments of two anonymous ASR readers were also helpful.

work force typically differs from that of their fathers. The difference between the two distributions is due, in part, to the changing occupational structure of society, but also to such factors as differential fertility, mortality and marriage rates (Duncan, 1966). Whatever the relative importance of these factors, the difference between the two distributions "forces" a certain amount of mobility and certain patterns of mobility, which are not indicative of the openness of society. This mobility often has been called structural mobility (Boudon, 1973; Matras, 1975).

Although the term "structural mobility" will be adopted in this paper, the use of this term is not meant to imply that the "forced" mobility can be traced to a change in the occupational structure over a specific period of time. First, as Duncan (1966) has pointed out, the fathers' occupational distribution does not represent a specific point in time. Second, factors other than the changing occupational structure, such as the differential fertility of the fathers, cause the origin and destination distributions to differ. Thus, the term "structural mobility" will be used to refer to the mobility resulting from all factors which cause the current distribution to differ from that of the fathers. Whatever the sources of such mobility, it is not due to equality of opportunity or the openness of society.

The general goal of mobility research has been to control for structural mobility in order to measure pure mobility, or exchange mobility, that is, mobility which is not due to differences between the origin and destination distributions. Critiques of methods designed to separate exchange mobility from structural mobility can be found in Duncan (1966), Blau and Duncan (1967) and Hazelrigg (1974b) and will not be reviewed here. Much of the effort at measuring exchange mobility has been inadequate or only partially successful. Recently, however, two techniques have been adopted which appear to control successfully for structural mobility. For example, a technique for the proportionate adjustment of contingency tables (Deming, 1943) has been used by Duncan (1966), Tyree and Treas (1974) and Hazelrigg (1974a), and Goodman's (1972) hier-

archical models for the analysis of contingency tables have been used by Hauser et al. (1975a).

The first premise of this paper is that although valid techniques are now available for comparing exchange mobility in different mobility tables, occupational mobility tables are inadequate for measuring or comparing vertical mobility, in either its exchange or structural components. The occupational categories, usually major census occupational groups, used to construct mobility tables are, strictly speaking, nominal categories and thus cannot be used to reliably assess vertical mobility. This premise is not meant to imply that those who use occupational mobility tables are interested only in vertical mobility. There may be sound reasons for studying occupational mobility per se. Carlsson (1958) has argued for the validity and utility of using aggregate occupational categories. Nevertheless, the importance of studying vertical mobility is evident from the fact that although persons who analyze mobility tables usually acknowledge the nominal nature of their data, they almost always include a discussion of upward and downward mobility (e.g., Hauser et al., 1975b). Typically, the major census detailed categories (or other categories) are ranked according to their average scores on some vertical dimension, such as Duncan's (1961) SEI. Duncan and Hodge (1963) reported that the major occupational categories accounted for about three-quarters of the variance in occupational SES among males in the labor force. This still leaves sizeable error in the measurement of an individual worker's status, however, and even in the rank ordering of individuals with respect to SES.

In addition to the measurement error that results from attempting to rank individuals according to the major occupational groups, the typical method of measuring vertical mobility only compounds the error. The typical method of computing upward mobility, for instance, involves counting all the individuals who move to a higher ranked category, with a move across one boundary counting the same as a move across two or more boundaries. Thus, this method of measuring

vertical mobility does not even use all of the ordinal information present in the data. Even if the number of category boundaries crossed were used as a measure of the vertical distance moved, there would still be considerable error involved since the average SEI distance between adjacent major occupational groups ranges anywhere from one to nineteen SEI points (Hauser et al., 1975b). In short, the use of occupational mobility tables to measure vertical mobility is faced with all of the limitations of ordinal scales, and the occupational categories only provide an imperfect ordering of individuals at that, since the categories are, strictly speaking, only nominal categories. Thus, an alternative to mobility tables is needed for measuring vertical mobility.

The development of a socioeconomic index (Duncan, 1961) and a prestige scale (Siegel, 1970) for the census detailed classification of occupations provided potentially fruitful means for the measurement of vertical occupational mobility. As Duncan and Hodge (1963) have pointed out, there is little question that these scales are more suitable for measuring vertical mobility than the census major occupational groups used in mobility tables. Although these scales may only be quasi-interval (particularly the prestige scale), they will be treated as interval scales when using the measures of vertical mobility to be presented in this paper. (The measures are just as appropriate for measuring education and income mobility, both of which are undoubtedly interval scales.)

In light of their potential fruitfulness, it is surprising how little these scales have been used for the study of vertical mobility.¹ Following the construction of the socioeconomic index (SEI), a reformulation of the basic problem to be studied occurred in the work of Duncan and his

colleagues. In Duncan and Hodge (1963), Duncan (1966) and, particularly, Blau and Duncan (1967), the orientation shifted from occupational mobility to one of explaining individual differences in occupational achievement, as measured by the SEI. Instead of using father's SEI score as a reference point from which mobility could be measured, father's SEI became one of several independent variables used to explain the variance in son's SEI. These multivariate models have come to be called models of the status attainment process.

The second premise of this paper is that the development of status attainment models, although extremely valuable in their own right, has diverted attention away from a legitimate concern with vertical mobility as a system characteristic. Instead of utilizing the SEI, or a prestige scale, to improve the measurement of the amount, rate and patterns of vertical mobility, as well as its exchange and structural components, these scales have been used almost exclusively in status attainment research. For those still concerned with the study of mobility (and the interest remains high) the conventional mobility table has continued to be the main vehicle, despite its limitations with respect to vertical mobility.

It is not claimed that status attainment models are irrelevant to the subject of mobility. The simple model showing son's status regressed on father's status implicitly contains much information on vertical mobility, some of which is occasionally noted. The difference between the father's mean and the son's mean indicates the average distance moved. Also, the standardized regression coefficient, the Pearson product-moment correlation, provides an index of mobility, or immobility, although no one has been very precise about what kind of mobility is being indexed. This is particularly problematic in light of the fact that a perfect correlation would not necessarily mean that there is no mobility. As Duncan (1966) has shown, the regression model also can be implicitly used to predict which sons will be upwardly mobile and which sons will be downwardly mobile. But, as Duncan (1966) has also stated, the regression model, as such, makes no direct statements about mobility. Although a

¹ Prestige scales occasionally have been used to construct mobility tables. For instance, Svalastoga (1959) used a Danish scale to construct mobility tables based on five aggregate prestige categories. Because of the necessity to aggregate data into a relatively small number of categories when constructing mobility tables, the measurement of social distance in such tables is not based on the full detail of the prestige scales.

great deal of information about mobility can be garnered indirectly from least-squares regression statistics, as we shall see, students of status attainment have made very little use of this information. In particular, they have paid no attention to the distinction between exchange mobility and structural mobility, a subject of great importance to those interested in mobility as a system characteristic.

In short, it can be concluded that the development of occupational status scales has had little or no effect on improving our measurement of vertical mobility, particularly with respect to exchange and structural mobility, because these scales have been used almost exclusively for status attainment research. Thus, it is time to use these scales to measure vertical mobility directly rather than to continue to make indirect inferences about mobility on the basis of their usage in regression models.

The third premise of this paper is that the conceptualization of social mobility has been rather unsophisticated and lacking in sociological insight. This seems to be true particularly with respect to vertical mobility. Social mobility is usually simply defined as a change in social position (Sørensen, 1975b). In mobility tables, social mobility means a change in occupation, as defined by the occupational categories chosen for the table. When we turn to vertical mobility, this definition of social mobility creates some problems.

If the occupational categories have been ranked according to some dimension of stratification and a person moves to a higher-ranked category, the move is defined as upward mobility. The trouble with this definition of vertical mobility is that it ignores the "social" aspect of social mobility. For instance, if the mobility table is constructed from major occupational groups, an intergenerational move from the managerial category to the professional category would be counted as one unit of upward mobility. This definition of upward mobility is based upon an absolute change of position and ignores the fact that in industrializing societies there is typically an expansion in the number of professional positions. Thus, it ignores the fact that

relative to other persons, a professional position does not rank as high in the destination distribution as in the origin distribution. The consequence of ignoring this fact may be seen more clearly if we consider a person who is in the professional category in both the origin and destination distributions. By conventional definitions, that is, in an absolute sense, such a person would be defined as stable with respect to vertical mobility. However, if the person's position relative to others were taken into account, say by looking at his percentile rank or some other standardized score, the person should be classified as downwardly mobile.²

Thus, it is seen that the conventional definition of vertical mobility is one of absolute mobility which ignores relative mobility. If we are to take the concept of social mobility seriously when discussing vertical mobility, it seems at least as important to study relative mobility as to study absolute mobility, if not more so. It could be argued that vertical "social" mobility should be defined as relative mobility, but this will not be done here. As will be seen, the conventional definition of social mobility will be called absolute mobility and, for reasons given below, relative mobility will be called exchange mobility.

To summarize the premises of this paper, it is believed that the study of vertical mobility has been retarded because of the continued reliance on mobility tables, because of the failure to explicitly exploit the detailed occupational status scales and because of the lack of a conception of relative vertical mobility. The remainder of this paper will attempt to define and measure absolute, exchange and structural

² To point out the fact that the percentile rank of *individuals* in professional occupations is not as high as the percentile rank of fathers in the same occupations is not necessarily to argue that professional occupations now rank lower, relative to other *occupations*, on income, education or "prestige." The available evidence indicates that the rankings or ratings of occupations have been rather stable over time (Hodge et al., 1966). However, the apparent immobility of occupations clearly does not preclude changes in the rankings of individuals who hold these occupations. Such changes in the relative statuses of individuals are eminently worth investigating.

vertical mobility with particular reference to occupational status mobility.

Definitions and Measures

In the definitions and measures of intergenerational vertical mobility to be presented, it will be convenient to refer to X as a score in the origin status distribution and Y as a score in the destination status distribution. By conventional definitions of social mobility, a person's vertical status mobility would equal $Y - X$. $Y - X$ gives both the absolute distance and the direction of the status move and will be called absolute mobility (not to be confused with the term "absolute value," which gives the numerical value of a real number irrespective of its sign). However, $Y - X$ reveals nothing about the person's mobility relative to other individuals in the status distributions. Due to the typical intergenerational shift upward in the status distributions, as indicated by a positive value of $\bar{Y} - \bar{X}$, a person with zero absolute mobility ($Y - X = 0$) actually would be downwardly mobile relative to others and a positive absolute mobility score ($Y - X > 0$) may or may not indicate upward mobility relative to others. Thus, in order to assess vertical mobility relative to others, a measure of a person's relative position in the origin and destination distributions is needed. Percentile ranks could be used but percentile ranks are only ordinal measures of status and, thus, a change in percentile rank would not indicate the relative status distance traveled.

In order to gain an interval measure of a person's relative position in a status distribution, a person's raw status score will be standardized with respect to the mean and standard deviation of the distribution, the conventional standard score used in regression analysis. Thus, a person's relative position in the X and Y distributions will be measured by $Z_x = (X - \bar{X})/s_x$ and $Z_y = (Y - \bar{Y})/s_y$, respectively, and his relative mobility will be indicated by $Z_y - Z_x$. The sign of $Z_y - Z_x$ will indicate the relative mobility direction, and the magnitude of

the difference will be proportional to the relative mobility distance.

A significant property of $Z_y - Z_x$ as an indicator of relative mobility is the fact that $\Sigma(Z_y - Z_x) = 0$. This zero-sum characteristic is usually associated with the conception of exchange mobility or circulation mobility, as it is sometimes called. It is assumed to result from the fact that persons are shifted upward and downward to adjust for differences in talent, skills and interests. Hazelrigg (1974b) has shown that when a mobility table is proportionately adjusted to a model of constant occupational structure, and therefore freed from structural influences on mobility, the number of person-steps upward will be equal to the number of person-steps downward. Thus, such an adjusted table has the zero-sum characteristic of circulation mobility. When using interval scales to measure mobility, a valid measure of exchange mobility should have the characteristics that the total upward mobility distance should equal the total downward mobility distance. $Z_y - Z_x$ has this zero-sum characteristic and, therefore, would seem to be a valid indicator of exchange mobility in this respect.

The other defining characteristic of exchange mobility usually given is that it is mobility that does not result from differences between the origin and destination distributions; it is distinguished from structural mobility. Since the Z_x and Z_y distributions are equal with respect to their means and standard deviations (which are equal to zero and one, respectively), $Z_y - Z_x$ can be treated as freed from structural influences, to the extent that differences between the origin and destination distributions can be reliably described by differences in their means and standard deviations.⁸ Thus $Z_y - Z_x$ appears to be a valid

⁸ Since standard scores are linear transformations of the raw scores, the standard score distributions will have the same shapes as the raw score distributions. Thus, any difference in the shapes of the origin and destination distributions will be a structural influence on mobility that is not eliminated by using standard scores. If the shapes of the distributions differ greatly, the use of standard scores to measure exchange

indicator of exchange mobility in respect to the second defining characteristic of exchange mobility.

Because of its zero-sum nature and its relative freedom from structural influences, $Z_y - Z_x$ will be treated as an indicator of exchange mobility. As a result of our interest in measuring relative mobility, we have arrived at a valid indicator of exchange mobility which truly reflects the "social" aspects of mobility.

Although $Z_y - Z_x$ is an indicator of exchange mobility, it does not provide a measure of exchange mobility distance in the metric of the status scale being used. To acquire such a measure, we will compute a person's score on Y who has experienced no exchange mobility. Since $Z_y = Z_x$ when there is exchange immobility, the destination status of a person with zero exchange mobility would be given by

$$Y' = s_y Z_x + \bar{Y}. \quad (1)$$

The expression for Y' given in (1) provides a very important reference point in our analysis which will be called the exchange immobility score. The deviation of a person's score from Y' provides the measure of exchange mobility distance, which can be written as

$$Y - Y' = s_y (Z_y - Z_x). \quad (2)$$

Since $\Sigma(Z_y - Z_x) = 0$, $\Sigma(Y - Y')$ will also equal zero and, thus, our measure of exchange mobility distance has the zero-sum characteristic. The expression for $Y - Y'$ also indicates that the exchange mobility of a person is, in part, a function of the amount of inequality in the population, as indicated by s_y . And finally, it is important to note that due to regression toward the mean, $Z_y - Z_x$ will tend to be negative for persons above the mean on X and positive for those below the mean on X. Thus, persons from above average origins will tend

to have downward exchange mobility and persons from below average origins will tend to have upward exchange mobility. The strength of this tendency will vary inversely with the strength of the correlation between X and Y.

The exchange immobility function also provides a reference point from which structural mobility distance can be computed. Since $Y' - X$ represents the distance a person would move who experiences no exchange mobility, this move would result from intergenerational structural change. Thus $Y' - X$ provides a measure of structural mobility which can be written as

$$Y' - X = (s_y - s_x)Z_x + (\bar{Y} - \bar{X}). \quad (3)$$

Examination of the expression for $Y' - X$ reveals several interesting facts about structural mobility. The amount of structural mobility a person experiences is a function of the changes in two basic structural parameters (the mean and standard deviation) and the person's relative position in the origin distribution. The mean structural mobility equals $\bar{Y} - \bar{X}$. Thus, when status attainment researchers note that the average mobility in their sample is equal to $\bar{Y} - \bar{X}$, they are taking note of the average mobility created by structural change in the status distributions. The standard deviation of structural mobility equals $s_y - s_x$, which is an indicator of the intergenerational change in inequality. Since the only variable in the expression for $Y' - X$ is Z_x , structural mobility will be perfectly correlated with X, with $r = +1$ when $s_y > s_x$ and $r = -1$ when $s_y < s_x$. Assuming that $\bar{Y} - \bar{X}$ is positive (which is typically the case), when inequality is increasing ($s_y > s_x$) persons from above average backgrounds will experience greater upward structural mobility than persons from below average backgrounds. The opposite will be the case when inequality is decreasing. Thus, an intergenerational increase in inequality favors persons from high status origins while a decrease in inequality favors those from low status backgrounds.

Perhaps the relationship between structural mobility and the origin distribution

mobility might lead to substantial errors. Although preliminary investigation suggests that the error may be relatively small for typical mobility distributions, we are as yet unable to present a satisfactory answer to this potential problem. Clearly, further investigation of this question is needed.

can be further clarified by looking at a simplified example. Imagine the following origin and destination distributions where

$\bar{Y} = \bar{X} = 50$, $s_x = 14.1$, $s_y = 21.2$, and $r = +1$.

X	Y	Y - X
70	80	+10
60	65	+5
50	50	0
40	35	-5
30	20	-10

Since the origin and destination distributions are perfectly correlated, all of the mobility is due to structural change. Since the means of both distributions are equal, the structural mobility results entirely from the increase in the standard deviations. This increase in inequality causes those who were below average on X to have downward structural mobility and those who were above average on X to have upward structural mobility, resulting in a perfect positive correlation between structural mobility and X. It should be noted that this example shows an exaggerated change in the standard deviation, if we are thinking in terms of occupational status.

By adding an intergenerational increase in the mean, the hypothetical example becomes more realistic. Suppose the X distribution remains the same but 15 is added to each Y making $\bar{Y} = 65$, but leaving s_y and r_{xy} unchanged.

X	Y	Y - X
70	95	+25
60	80	+20
50	65	+15
40	50	+10
30	35	+5

Now the intergenerational increase in the mean is sufficiently large to make each person have upward structural mobility. However, although the average structural mobility is $\bar{Y} - \bar{X} = 15$, the increase in the standard deviation causes those with higher scores on X to have greater structural mobility.

It is also instructive to consider the rela-

tionship between exchange and structural mobility. The covariance of exchange and structural mobility, which is given without proof, can be written as

$$s_{(y-y')(y'-x)} = s_y(s_x - s_y)(1 - r_{xy}). \quad (4)$$

The term $s_x - s_y$ indicates that the covariance between exchange and structural mobility will be positive when inequality is decreasing and negative when inequality is increasing (assuming a positive correlation). Since persons from below average origins tend to have upward exchange mobility and since they will have greater structural mobility than persons from above average origins when inequality is decreasing, structural and exchange mobility will covary positively when $s_y < s_x$ and thus complement one another. However, in the more typical case where inequality of occupational status is increasing, the downward exchange mobility tendencies of persons from above average backgrounds will be ameliorated somewhat by their greater than average upward structural mobility. Whenever inequality is changing, exchange and structural mobility will have some covariance.

Given the measures of exchange and structural mobility which have been presented, it is easily recognized that absolute mobility is simply the sum of exchange mobility and structural mobility

$$(Y - Y') + (Y' - X) = Y - X. \quad (5)$$

The manner in which exchange and structural mobility combine to give absolute mobility is shown in Figure 1. The data displayed in Figure 1 are from the 1962 OCG subsample of white males (Duncan et al., 1972). The solid line $Y = X$ represents the absolute immobility line, the dashed line $Y' = s_y Z_x + \bar{Y}$ is the exchange immobility line and the dotted line $\hat{Y} = a + bX$ is the least-squares prediction of Y. For any given score on X, the vertical distance between the Y' line and the \hat{Y} lines indicates the expected exchange mobility, the distance between the Y' line and $Y = X$ equals the structural mobility and the distance between the \hat{Y} line and $Y = X$ equals the ex-

pected absolute mobility. The figure shows upward structural mobility for all values of X , with the amount of structural mobility increasing as the level of X increases. The least-squares line and the exchange immobility line intersect at approximately $X = \bar{X} = 28$. Below the mean of X , it can be seen that both exchange mobility and absolute mobility tend to be upward. Next, observe the area above the mean of X but below $X = 50$, the approximate value of X at which the line $Y = X$ and the \hat{Y} line intersect. For this range of values of X (from 28 to 50), exchange mobility tends to be downward but absolute mobility is still upward. Therefore, although these men

from above average backgrounds tend to be losing ground relative to others, they are still experiencing absolute upward mobility due to their structural mobility. And, finally, those men with background scores of 50 or higher (at least one standard deviation above the mean) are experiencing both downward exchange mobility and downward absolute mobility, despite the fact that they have the greatest structural mobility of the three categories of men discussed. Their status (\hat{Y}) still tends to be higher than the others, of course. The negative covariance between structural and exchange mobility is clearly displayed in Figure 1. The vertical distance between Y' and $Y = X$ (structural mobility) becomes

Figure 1. Relationships between Absolute, Exchange and Structural Mobility for White Males, 1962

increasingly positive as the vertical distance between Y' and \hat{Y} (expected exchange mobility) changes from positive to increasingly negative.

Definitions and measures of exchange, structural and absolute mobility have been given at the individual level, and their characteristics and relationships have been discussed. Absolute mobility is seen to be a function of exchange and structural mobility. Structural mobility results from changes in the demand for labor as well as from differential fertility, mortality and marriage rates. No attempt has been made to explain individual differences in exchange mobility, but exchange mobility is assumed to result from individual differences in talents, skills and desires. Since the goal of this paper is not to explain vertical mobility but to define and measure it in its several components, the next step is to develop measures which describe the aggregate mobility of the entire population or system.

The mean is not a very useful statistic for describing the average amount of absolute and exchange mobility since the downward mobility moves tend to cancel out the upward moves in $\Sigma(Y - X)$ and do so exactly in $\Sigma(Y - Y')$. We could compute the mean of the absolute values $|Y - X|$ and $|Y - Y'|$, but absolute values are not mathematically tractable to work with. Our choice of a single statistic to describe the aggregate amount of each type of mobility is to compute the square root of the second moment of each mobility distribution. As we shall see, this measure can be meaningfully expressed and calculated from readily available statistics such as the means and standard deviations of the origin and destination distributions and the product moment correlation between the distributions.

Although our procedure will be to take the square root of the second moment in order to convert our measure of the amount of mobility back into the original metric, for the sake of simplicity the square root sign will be omitted in the following presentation of formulas. The second mo-

ment of the absolute mobility distribution is given by

$$\Sigma(Y - X)^2/N = (\bar{Y} - \bar{X})^2 + s_y^2 + s_x^2 - 2s_y s_x r. \quad (6)$$

Thus, our measure of absolute mobility can be expressed in terms of the structural characteristics of the origin and destination distributions, as measured by the means and standard deviations, and the correlation between the distributions (which will be defined as an index of exchange immobility). However, since the effects of the statistics in equation (8) can be seen more clearly in the formulas to be presented for the aggregate exchange and structure mobility, as well as in equation (4) for the covariance between exchange and structural mobility, formula (6) will not be discussed further.

The second moment of the exchange mobility distribution can be written as

$$\Sigma(Y - Y')^2/N = 2s_y^2(1 - r). \quad (7)$$

Thus, it can be seen that the amount of exchange mobility in a population is a function of the interaction between the variance of the destination distribution and the correlation between the origin and destination distributions. The greater the inequality of status, the greater will be exchange mobility, and the higher the correlation, the less will be exchange mobility. As the reader has probably suspected by now, $1 - r$ can be used for comparative purposes as an index of exchange mobility. This was recognized by Rogoff (1966:213) who pointed out that the coefficient of correlation standardizes for differences between the means and standard deviations of the fathers' and sons' occupational status, and thus controls for structural changes. Although $1 - r$ can range mathematically from 0 to 2, practically speaking we would never expect to find a negative correlation and, thus, the index can be interpreted on a scale from 0 to 1. The index will equal one when there is "perfect" mobility, that is, statistical independence between X and Y as indicated by $r = 0$.

The second moment of the structural

mobility distribution can be expressed rather simply as

$$\Sigma(Y' - X)^2 / N = (\bar{Y} - \bar{X})^2 + (s_y - s_x)^2. \quad (8)$$

This expression indicates that the amount of structural mobility in a population is a function of structural changes in the average level of status and changes in the inequality of status.

Although absolute mobility equals the sum of exchange mobility and structural mobility at the individual level, such is not the case for our measures at the societal level, unless the covariance between exchange and structural mobility is zero. It can be shown that the second moment of absolute mobility is equal to the sum of the second moments of exchange and structural mobility plus twice their covariance:

$$\begin{aligned} \frac{\Sigma(Y - X)^2}{N} &= \frac{\Sigma(Y - Y')^2}{N} \\ &+ \frac{\Sigma(Y' - X)^2}{N} + 2s_{(Y-Y')(Y'-X)}. \end{aligned}$$

The expression for the covariance was given in equation (4), which shows that when inequality is increasing, the covariance of exchange and structural mobility will be negative. Thus, it is possible for the total amount of absolute mobility to be less than the sum of exchange and structural mobility and, in some cases, as will be seen, the amount of absolute mobility may be less than the amount of exchange mobility.

This concludes the presentation of definitions and measures of absolute, exchange, and structural mobility. Hopefully, we have shown that valid population measures for the components of mobility can be computed easily from three basic types of statistics readily available from regression analysis outputs (the means, the standard deviations and the correlation). We have given these statistics meaningful interpretations with respect to mobility in its several forms.

It might be objected that since these statistics are present in regression models of status attainment, they add nothing new to our knowledge in the form introduced here.

For instance, the least-squares prediction of Y can be rewritten in terms of these basic statistics as follows:

$$\hat{Y} = \bar{Y} + \frac{rs_y}{s_x} (X - \bar{X}).$$

Thus, it can be seen how a person's expected absolute position on Y is determined by the structural and exchange aspects of the X and Y distributions. However, a comparison of two populations with respect to their regression equations in this form, or in any form for that matter, could not provide answers to such basic questions as "which society has the most absolute mobility, the most exchange mobility, and the most structural mobility?" It can only be reiterated that status attainment analysis is not the same as mobility analysis. They are closely related, however. It is believed that the strength of this paper is to show how the basic statistics from regression analysis can be brought directly to bear on problems still being struggled with in the analysis of mobility tables, particularly problems in the analysis of vertical mobility.

Occupational Status Mobility

The measures of absolute, exchange and structural mobility will now be used to examine occupational status mobility in the United States. Occupational status is measured by Duncan's (1961) Socioeconomic Index (SEI). The mobility of black and white males will be analyzed for the years 1962 and 1972-1974. The mobility of black and white females will be analyzed only for 1972-1974. The data are for persons 25 to 64 years of age in the experienced civilian labor force. The 1962 data are from the Occupational Changes in a Generation (OCG) survey as reported in Duncan et al. (1972: Tables A.1 and A.3). The data for 1972-1974 are from the combined General Social Surveys of 1972, 1973 and 1974 conducted by the National Opinion Research Center (NORC). The components of mobility are given in Table 1, along with the means, standard devia-

Table 1. Components of Occupational Status Mobility of the Experienced Civilian Labor Force, 25 to 64 Years of Age, by Sex, Race and Year

	1962		1972-1974		1972-1974	
	Males		Males		Females

* Absolute, exchange and structural mobility equals the square root of the second moment of the respective mobility distributions, as given in equations (6), (7) and (8).

tions and correlations from which the mobility components were computed.⁴

⁴ Since mobility trends between 1962 and 1972-1974 will be discussed, the comparability of the 1962 Current Population Survey (CPS) data and the 1972-1974 NORC data are of some concern. Differences in sampling methods, item wording and method of enumeration could make comparisons unreliable. As a check on the comparability of the CPS and NORC data, we will compare the means and standard deviations of father's and son's SEI with those from the 1973 CPS replicate of the OCG study as reported in Featherman and Hauser (1975). A difference between the CPS and NORC methods of coding "father's" occupation can be expected to cause some discrepancies between these statistics. The CPS asked for mother's or other female head's occupation when the respondent was not living with his father or father substitute at age 16, whereas NORC did not elicit the occupation of respondent's mother or other female head under this circumstance. Thus, the NORC data on "father's" occupation does not include female head's occupation.

Blau and Duncan (1967:33) indicate that in the 1962 CPS data, "father's" occupation pertains to a male head in 93 percent of the cases and to a female head in seven percent of the cases. Thus, we would estimate that the NORC data does not cover about seven percent of the population covered by CPS. Actually, 11.5 percent of the NORC males in the ECLF came from female headed families, but it would be expected that not all of these female heads had jobs. Knowing the direction of the NORC undercoverage allows us to predict the direction of NORC-CPS discrepancies. Since Duncan et al. (1972) report that the average SEI of males,

both black and white, from female headed families is several points lower than that of males from intact families, we would expect the black and white means in the NORC data to be somewhat higher than in the 1973 CPS data. (In order to insure that the means and standard deviations in Table 1 are based on the same number of cases as the correlations, males from female headed families were excluded from the calculations for current SEI.) Since it is reasonable to assume that the average SEI of female heads should also be lower than the average SEI of male heads, we would also expect the mean SEI for "father's" occupation to be higher in the NORC data than in the CPS data, particularly for blacks who are more likely to come from female headed families (22 percent of the blacks, versus 10 percent of the whites, are from female headed families).

Both of these predictions are borne out by the data. The mean SEI's for the CPS and NORC white males are 42.6 and 44.3, respectively, and 25.8 and 26.4 for the black males. The means for father's SEI in the CPS and NORC surveys are 30.2 and 32.7 for white males, and 16.0 and 19.9 for the black males. Note that the CPS-NORC discrepancy is greatest for the black "father's" since there is a greater proportion of blacks from female headed families. Since $\bar{Y} - \bar{X}$ contributes to structural mobility, the NORC data appear to underestimate black structural mobility. The NORC "error" with respect to $\bar{Y} - \bar{X}$ for whites is quite small, however. The NORC standard deviations for respondent's SEI are about one point lower than the CPS standard deviations, for both blacks and whites (24.2 versus 25.2 for whites and 19.8 versus 20.4 for blacks). With respect to "father's" SEI, the NORC and CPS standard deviations are about equal for whites (22.9 and 22.6, respectively), while the NORC standard deviation for blacks is

There are several striking characteristics of the mobility data which should be noted before turning to a comparison of the groups and years. In both 1962 and 1972-1974, each group experienced an average intergenerational increase in status, as indicated by $\bar{Y} - \bar{X}$. This upward shift in status is greatest for white males. An intergenerational increase in status inequality, as indicated by $s_y - s_x$, also occurred for all groups except white females. The increase in inequality results in a negative covariance between structural and exchange mobility. These intergenerational structural changes caused a substantial amount of structural mobility, equaling about half a standard deviation of the status distribution of white males. Nevertheless, the amount of exchange mobility is consistently more than twice as great as the amount of structural mobility. The index of exchange mobility ($1 - r$) is high for all groups, equaling at least .6 in each case. Thus, it is clear that exchange mobility contributes much more to the amount of absolute mobility than does the not inconsequential amount of structural mobility.

Turning to the mobility of specific

2.5 points higher than the CPS standard deviation (16.3 versus 13.7, respectively). Since $s_y - s_x$ contributes to structural mobility, the NORC data again would appear to underestimate the structural mobility of blacks. Featherman and Hauser (1975) do not report the correlation between father's and son's SEI, so the NORC correlation cannot be checked.

In general, the NORC-CPS discrepancies appear small. Since they are small and in the direction predicted by the omission of "father's" SEI for female heads in the NORC surveys, it appears that valid comparisons between the 1972-1974 NORC surveys and the 1962 CPS survey may be made, when proper caution is exercised with respect to the known discrepancies. The most serious discrepancies are for the mean and standard deviation of the black fathers' SEI. These discrepancies appear to lead to a significant underestimate of black structural mobility. However, despite this discrepancy and other smaller ones, the major conclusions concerning the comparisons and trends of black and white mobility will not be affected. In addition, much of the analysis in this paper does not involve trend analysis, and thus the omission of "father's" occupation for female heads does not invalidate the analysis, as long as this omission is kept in mind.

groups, white males, who are a majority of the labor force, will be examined first. White males have a greater amount of exchange mobility, structural mobility and absolute mobility than either of the other groups. When the mobility of white males in 1972-1974 is compared with that in 1962, however, there does not appear to be any significant change. The ever so slight reduction in structural mobility and increase in exchange mobility are too small to be reliable or of interest. The slight increase in exchange mobility resulted from the smaller correlation in 1972-1974, but the interperiod change in the correlation is significant at only the .15 level. The change in absolute mobility is somewhat greater than the changes in exchange and structural mobility. It is interesting to note that the increase in absolute mobility resulted primarily from a decrease in the covariance between exchange and structural mobility, rather than from a change in either of the latter. The decrease in the covariance occurred because the increase in intergenerational inequality ($s_y - s_x$) was smaller in 1972-1974 than in 1962. The smaller increase in inequality meant that men from above average backgrounds did not have as great a structural mobility advantage over men from below average backgrounds in 1972-1974 as they did in 1962. Thus, the negative covariance between exchange and structural mobility decreased and, consequently, the amount of absolute mobility increased. The increase in absolute mobility is not very great, however, and the mobility of white males in 1972-1974 is more striking for its similarity to that in 1962 than for its differences.

If there was little or no change in white mobility, the interperiod changes in black mobility were rather dramatic. The absolute mobility of black males increased by 34 percent, exchange mobility increased by 31 percent and structural mobility increased by fully 155 percent. The sharp increase in structural mobility resulted primarily from the larger intergenerational difference in average status ($\bar{Y} - \bar{X}$) in 1972-1974, although the slight interperiod increase in $s_y - s_x$ (the intergenerational increase in inequality) also contributed to

the increase in structural mobility. The average status of the black sons in 1972-1974 was 7.5 points higher than that of their fathers, whereas the difference between fathers and sons was only 1.6 points in 1962.

Whereas the increase in structural mobility resulted primarily from the increase in $\bar{Y} - \bar{X}$, the increase in exchange mobility resulted solely from the interperiod increase in status inequality (s_y). The index of exchange mobility ($1 - r$) of black males did not change between 1962 and 1972-1974, but s_y increased by 29 percent and, thus, an increase in exchange mobility occurred. Since both exchange mobility and structural mobility increased, both contributed to the increase in the absolute mobility of blacks. However, although structural mobility increased by a greater percentage than did exchange mobility, exchange mobility increased by a greater amount and contributed somewhat more to the increase in absolute mobility than did structural mobility. Since the increase in exchange mobility was due to the increase in s_y indicating that black males were receiving a wider range of positions in the status hierarchy in 1972-1974 than in 1962, the single most important contributor to the increase in absolute mobility was the increase in inequality among black workers.

Having examined the change, or lack of change, in the mobility of black and white males separately, the mobility of blacks and whites will now be compared. Three generalizations seem clear. First, blacks have less mobility than whites. Second, the makeup or nature of black mobility is different. Third, black mobility is becoming more similar to white mobility.

In order to facilitate racial comparisons, Table 2 gives the ratios of black status to white status and black mobility to white mobility. In both 1962 and 1972-1974, black males had lower and less varied status than whites. This is a well-known fact. Blacks also came from lower and less varied status backgrounds in both years. Although black males showed significant gains relative to whites over the 10-12 year period, the racial gap in average status re-

Table 2. Ratio of Black Status to White Status and Black Mobility to White Mobility for Males in the Labor Force, 25-64 Years of Age, in 1962 and 1972-1974

Exchange	.75	.95
Structural	.24	.63

mains great. Featherman and Hauser (1975) present a more detailed analysis of the changes in racial status attainment.

Although the racial differences in mobility are not as great as the differences in status, in each year the exchange mobility, structural mobility and absolute mobility of blacks is less than that of whites. Black structural mobility is smallest relative to whites while exchange mobility is greatest. Also, just as with status attainment, the amount of black mobility more nearly approximated that of whites in 1972-1974 than in 1962. This is particularly true for the amount of black exchange mobility, which nearly reached parity with white exchange mobility. However, although the racial difference in the amount of exchange mobility is slight in 1972-1974, the makeup of this mobility is different for blacks than for whites. The extremely high index of exchange mobility of black males contributes more to their exchange mobility than is the case for whites. Conversely, the relatively greater amount of status inequality of whites contributes more to their exchange mobility. The reason that black exchange mobility nearly equaled white exchange mobility in 1972-1974 is that the variation in black status increased relative to that of whites while the black index of exchange mobility ($1 - r$) remained high, both absolutely and relative to whites. In other words, while the black status structure has become more nearly like the white structure (although significant differences remain), a closer articulation between father's and son's status among blacks has

not occurred. Thus, we should not infer from the racial similarities in the aggregate amount of exchange mobility that blacks have achieved some sort of equality with respect to mobility.

Although blacks experienced large gains in structural mobility relative to whites between 1962 and 1972-1974, the amount of black structural mobility was still only .63 as large as that of whites in 1972-1974. The composition of black structural mobility in 1972-1974 was also different than that of whites. Whereas white structural mobility resulted almost solely from the intergenerational increase in status ($\bar{Y} - \bar{X}$), black structural mobility was significantly affected by the intergenerational increase in inequality ($s_y - s_x$), as well as by the intergenerational increase in average status. In other words, the black occupational structure was changing in a more complex way, relative to their fathers, than was the case for whites, and thus the nature of structural mobility is different for blacks.

The black gains in exchange and structural mobility relative to whites naturally lead to black gains in the amount of absolute mobility. But again we note racial differences in the process of mobility. The increase in absolute mobility relative to whites was not as great as might have been expected on the basis of the black gains in exchange and structural mobility. This is due to the fact that the negative covariance between the exchange and structural mobility of blacks in 1972-1974 was considerably greater than the negative covariance for whites. The greater negative covariance for blacks resulted from the very same factors that made black exchange mobility and structural mobility different in nature from that of whites, that is, from a higher index of exchange mobility ($1 - r$) and a greater intergenerational increase in inequality ($s_y - s_x$) among blacks. Thus, the tendency for males with downward exchange mobility to have greater upward structural mobility was greater among blacks than among whites and led to less absolute mobility among blacks (relative

to whites) than would otherwise have been expected.

In summary, the comparison of black and white mobility has shown that blacks experience less mobility than whites, although the differences are diminishing. The comparison has also shown racial differences in the nature of exchange mobility and structural mobility, as well as differences in the relationship between the two components of mobility. Thus, not only do blacks and whites differ with respect to the amount of mobility, they also show clear differences in the process of mobility.⁵

The occupational status mobility of females in 1972-1974 will now be examined. Although white females experience less mobility of each type, than white males, the mobility of white females is more similar to that of white males than is the case for black males. The exchange mobility of white females is only .91 as great as the exchange mobility of white males. Since there is little or no difference between the indices of exchange mobility of white males and females, the smaller amount of exchange mobility among white females is due to the fact that they have less variation in status than white males (the female standard deviation being only .9 as large as the male standard deviation). The smaller white female standard deviation reflects the fact that they are less likely to have high

⁵ As indicated in footnote 4, the discrepancies between the 1972-1974 NORC survey and the 1973 CPS would not affect these conclusions. The 1973 CPS data suggest that there would be little change in the relative amounts of black and white exchange mobility, nor in the racial differences in the makeup of exchange mobility. Although the 1973 CPS suggests a greater amount of black structural mobility, white structural mobility would still be somewhat greater and, more importantly, the racial differences in the makeup or process of structural mobility would remain. That is, black structural mobility would still be affected much more by $s_y - s_x$, and much less by $\bar{Y} - \bar{X}$, than would white structural mobility. These racial differences still would cause a greater negative covariance between exchange and structural mobility for blacks than for whites and lead to less absolute mobility, relative to whites, than would be expected from the racial differences in exchange and structural mobility.

and low status occupations than white males (Treiman and Terrell, 1975; McClendon, 1976).

The structural mobility of white females is also less than that of white males. The smaller female structural mobility results from the fact that they experience a smaller intergenerational shift in average status ($\bar{Y} - \bar{X}$). This, in turn, results from the fact that white females in the labor force come from a somewhat higher status background than white males. Since white males and females have about equal occupational status, on the average, white females experience less structural mobility than white males.

The nature of female structural mobility is also somewhat different from that of males. White males and females come from equally varied backgrounds. However, females have less varied status than their fathers while males have more varied status than their fathers. Thus, white males experience an intergenerational increase in status inequality ($s_y - s_x$) while females experience a decrease in inequality. This produces a positive correlation between structural mobility and father's status for males and a negative correlation for females. In other words, males from high status backgrounds have more upward structural mobility than males from low status backgrounds, whereas females with high status fathers have less structural mobility than those with low status fathers. The intergenerational decrease in female inequality also produces a positive covariance between exchange and structural mobility, as opposed to the more typical negative covariance for white males. The female positive covariance means that they have a greater amount of absolute mobility, relative to white males, than would otherwise be expected, although the absolute mobility of white females is still less than that of males.

In summary, although white females experience less mobility than white males, the differences are not great. The differences result primarily from the fact that white females come from slightly higher status backgrounds and have less varied occupational status than white males. That is, the

sex differences in mobility result from differences in the male and female occupational structures, not from differences in the index of exchange mobility. These structural differences not only result in somewhat less female mobility, but also lead to an interesting, if not overly pronounced sex difference in the process of mobility, as indicated by the positive covariance between the exchange and structural mobility of females.

The mobility of black females will not be examined in detail because the sample size ($N = 81$) is too small to be reliable. The data suggest that the mobility of black females is different from that of the previous groups analyzed. With respect to the amount of exchange, structural and absolute mobility, black females are similar to black males. However, the makeup of the structural and exchange components of black female mobility differs from that of black males. Black females appear to have a lower index of exchange mobility than black males and, with respect to structural mobility, they appear to experience a greater intergenerational increase in inequality.

Educational Mobility

It will be instructive to examine educational mobility, which differs in several interesting ways from occupational status mobility. The NORC General Social Surveys of 1972-1974 will be used to estimate the educational mobility of white males and females and black males and females. The analysis will not be confined to members of the labor force, but will instead include all respondents 25 to 64 years of age. The means and standard deviations of father's education and respondent's education, the correlation between father's and respondent's education, and the exchange, structural and absolute mobility components are given in Table 3.

The most obvious difference between educational mobility and occupational status mobility is that educational structural mobility is much greater, relative to exchange mobility, than was the case for status mobility. This is true for each group, with structural mobility actually being greater

Table 3. Components of Educational Mobility of Persons 25 to 64 Years of Age by Sex and Race, 1972-1974

	Males		Females	
	Whites	Blacks	Whites	Blacks
\bar{Y}	12.8	10.7	12.3	10.8
\bar{X}	9.0	6.9	8.2	6.7
s_y	3.5	4.1	2.5	3.3
s_x	4.3	4.3	4.0	4.5
r	.45	.44	.51	.52
N	1,002	115	1,118	114
Mobility				
Absolute	5.6	5.9	4.7	5.7
Exchange	3.7	4.3	2.5	3.2
Structural	3.9	3.8	3.4	4.3
Covariance	1.5	.5	1.8	1.9

than exchange mobility for each of the groups except black males. Part of the reason for the relatively great amount of structural mobility is that the index of exchange mobility is lower for each group than was the case for occupational status mobility. But this is not the only reason. The structural changes in the educational distribution are greater than the structural changes in occupational status. For each group, the percentage increase in mean years of school completed is greater than the percentage increase in mean occupational status. Thus, structural changes in schooling (i.e., an increase in the amount of schooling and a declining inequality of schooling) contribute more to the absolute amount of educational mobility than structural changes in occupational status contributes to absolute status mobility.

A second striking feature of educational mobility is the intergenerational decline in inequality ($s_y < s_x$). This decline means that structural mobility is negatively correlated with father's education. Thus, persons from above average educational backgrounds will have less upward structural mobility than those from below average backgrounds. Since the decline in inequality is greater for females, and greatest for white females, this process is most pronounced for them. The decline in inequality also, of course, means that there is a positive covariance between exchange and structural mobility, as opposed to the nega-

tive covariance which is typical of occupational status mobility. Thus, persons who are upwardly exchange mobile with respect to schooling will tend to have more upward structural mobility. Since exchange mobility and structural mobility tend to reinforce each other, the aggregate amount of absolute mobility is greater than would otherwise be expected.

Several factors also stand out with respect to exchange mobility. As mentioned above, the index of educational exchange mobility is lower than the index of occupational exchange mobility; and the index of educational mobility is lower for females than for males. This is usually attributed to the fact that education is more of a luxury for females and more of a necessity for the occupational pursuits of males (Treiman and Terrell, 1975; McClendon, 1976). Because of their lower index of exchange mobility, females have less exchange mobility than males. They also have less exchange mobility because the amount of female schooling does not vary as much as that of males. This is mostly true for white females, who have considerably less exchange mobility than the other groups. In fact, white females also have less structural mobility and less absolute mobility, making them the least mobile of the groups.

In summary, the most distinctive features of educational mobility, as compared to occupational status mobility, are the relatively greater amount of structural mobility, the lower index of exchange mobility and the positive covariance between exchange and structural mobility.

Summary and Conclusion

This paper has argued that the study of vertical social mobility has suffered from overreliance on occupational mobility tables, from underutilization of occupational status scales and from failure to conceptualize social mobility as relative mobility. Definitions and measures of absolute mobility, exchange mobility and structural mobility were then given at the individual level. Each type of mobility involves the idea of mobility distance on some relevant vertical dimension and, thus, the measures for each type of mobility assume that an

interval scale for the dimension exists. Exchange mobility was conceptualized as relative mobility and a measure was given which has a zero sum nature and is relatively free from structural influences. Structural mobility was then defined as the distance a person would move if the person experienced no exchange mobility. It was seen that the sum of an individual's exchange mobility and structural mobility is equal to his absolute mobility, that is, the distance between the person's absolute scores in the origin and destination distribution.

Measures of aggregate population mobility were then given for each type of mobility. It was seen that the three aggregate measures could be computed from five readily available statistics, the means and standard deviations of the origin and destination distributions and the correlation between the distributions. These measures were applied to intergenerational occupational status data for the United States. There was little or no evidence that the mobility of white males had changed between 1962 and 1972-1974. However, a substantial increase in the mobility of black males was found for this period. The mobility of black males was still considerably different from that of white males in 1972-1974, both with respect to the amount of mobility and the patterns of mobility. Although several interesting differences were found between the mobility of white males and females, the mobility of white females was more similar to that of white males than was the case for black males. Finally, aggregate educational mobility was briefly examined and compared to occupational status mobility. Several interesting differences were found, most important of which was the larger amount of structural mobility, relative to exchange mobility, in educational mobility.

Although the application of the measures presented in this paper has been limited to aggregate interperiod and intergroup comparisons within a single society, this limitation was dictated only by considerations of space. There are at least two obvious directions in which the analysis could be expanded. First, each type of mo-

bility could be analyzed in greater depth than the aggregate summaries given in this paper. For instance, questions concerning the symmetry of a mobility distribution might be of interest. Is long range mobility more likely in an upward direction or in a downward direction? This question concerning the skewness of the mobility distribution can be easily answered from the raw mobility data. Another question of interest concerns the degree to which aggregate mobility is made up of a few persons making relatively long-distance moves versus many persons making relatively short-distance moves. This question concerns the kurtosis of the mobility distribution, which can also be easily computed from the raw data. Unfortunately, neither skewness nor kurtosis can be computed from the means, standard deviations and correlation, as could aggregate mobility. Preliminary examination of these questions indicates that, with respect to occupational status mobility, the exchange mobility distribution and absolute mobility distribution for all members of the labor force in 1972-1974 are both approximately normally distributed. However, both distributions appear more peaked than normal for the black male subpopulation.

The second obvious direction in which the analysis could be expanded is to cross-societal comparisons of mobility. Until very recently, such comparisons have been impossible with respect to occupational status mobility because of the lack of a standardized status scale. Now, however, the publication of Treiman's (1975) Standard International Occupational Prestige Scale makes such comparative studies possible, at least for occupational prestige. Treiman (1975) has recoded the occupational data from mobility studies in at least eight different nations into the Standard Prestige Scale. If we add the occupational mobility data for Costa Rica and Haiti, which have been recoded into the Standard Prestige Scale by Lin and Yauger (1975), there appear to be at least ten nations for which absolute, exchange and structural prestige mobility could be compared.

Of course, the ultimate goal of cross-national studies is not just to compare

rates, amounts and patterns of mobility, but to find societal correlates of mobility. There has been considerable interest in the relationship between industrialization and mobility. For instance, although Hazelrigg and Garnier (1976) found no relationship between energy consumption and the rate of circulation (exchange) mobility for seventeen nations, they did report a moderately strong correlation between energy consumption and the rate of mobility when inter-county variations in the shape of the origin occupational distribution were not controlled, using rather crude (nonmanual, manual, farm) mobility tables. Their research clearly suggests that different components of mobility have different relationships to the level of industrial development. There also must be other societal characteristics, in addition to the level of development, which are relevant to mobility. It is hoped that the individual and aggregate measures of exchange, structural, and absolute mobility proposed in this paper will help specify these relationships.

A THEORETICAL MODEL FOR THE INTERPRETATION OF TABLES OF SOCIAL MOBILITY *

JAMES C. MCCANN

*Center for Studies in Demography and Ecology
University of Washington*

American Sociological Review 1977, Vol. 42 (February):74-90

This paper describes a procedure for analyzing tables of social mobility. The method is deduced from a few simple postulates relating to the mobility process. The major assumption is that sons may be ranked on a single dimension of status and that their occupational attainment is determined by their ranking on this dimension and by current labor needs. A priori specification of the general nature of the distribution of sons along this dimension is an operational requirement of the model. The procedures are applied to the intergenerational mobility tables of Britain and Denmark. The results show that, in large measure, the tendency of sons to take positions similar to those of their fathers can be accounted for without recourse to a principle of status inheritance. Another advantage of these procedures is that, within the framework of the model, they permit the effects on mobility of changing labor requirements to be separated from the effects due to the openness or fluidity of the social system.

The intergenerational mobility table or cross-classification of sons' and fathers' statuses typically is constructed to show the extent to which sons in a population inherit or profit from the social and economic positions of their fathers. In general, these tables are used for comparative purposes to determine whether a principle of

inheritance operates more strongly in one population than in another or whether it is changing over time. The degree of social inheritance is taken to be strong insofar as the statuses of sons are positively influenced by those of their fathers. Unfortunately, statements based on the comparison of mobility tables typically must be qualified in that the marginal distribution of statuses generally will differ from population to population. If, as in standard analyses, the marginals are taken as given or as logically prior to the allocation of sons, similar or proportional cross-tabulations cannot be expected. As a consequence, the same principle of inheritance operating in different contexts will typically give rise to different allocations. The problem is dis-

* The comments and suggestions of Hubert M. Blalock, Philip Blumstein, Christine Bose, James Coleman, Otis Dudley Duncan, Lowell Hargens, Stanley Lieberman, Samuel Preston, Alberto Palloni and Ronald Pyke were helpful in the development of this paper. The suggestions of an anonymous reviewer were also of considerable assistance. Robert Eichenlaub developed the numerical procedures and wrote the computer program which yielded the results presented here.

cussed in an extensive literature. See, for example, Lipset and Zetterberg (1956) and Boudon (1973).

It is important to note that the degree to which a principle of inheritance operates in a population cannot be inferred straightforwardly from its mobility table. The observed cross-tabulation is an outcome of a rule of allocation and, in general, a plurality of rules may be constructed which will yield the outcome. Moreover, some of these will reflect a stronger principle of inheritance than will others. As an illustration, consider the following "observed" allocation:

		Son's Position		
		High	Low	Σ
Father's Position	High	50	50	100
	Low	50	100	150
	Σ	100	150	250

In the context of the given marginal distributions, this allocation would arise if (1) the chance that a son of low origins will attain a high position is always two-thirds those of sons of high status origins or if (2) 50% of high status positions are reserved for sons of low status backgrounds. In general, the first principle would be taken as more consistent with a principle of inheritance than the second. The indeterminacy which this example illustrates cannot be escaped unless the interpretation of mobility tables is approached with an explicit theory regarding the allocation of human labor.

Inherited Advantages, Competition, and Career Outcomes

It is reasonable to conceive of occupational mobility as a simple two-stage process. Prior to settling into careers, sons accumulate a set of advantages (or disadvantages) which bear on their acceptability for and desire to attain the more prestigious occupations. The value of the advantages a son will accumulate is conditioned by the position of the family in which he was born and reared. In general, sons of families of high standing are relatively well-educated and, perhaps, more socialized to the demands of the more responsible employ-

ments than sons of meaner origins. This is not to exclude purely ascriptive influences. Family name and family connections, for example, can figure into the sum of an individual's advantages. Sons are recruited to the more prestigious positions on the basis of their accumulated advantages or "quality" with the highest class recruiting the most qualified sons, the next highest classes choosing the most qualified among those not recruited to the highest class, and so forth. Under this formulation, the degree of status inheritance lies in the differences in the distribution of quality of sons of varying origins. It should be noted that the word "quality," as used here, is assigned a very broad definition. Stated strictly, the quality of a son's labor is taken to be high insofar as he can compete successfully for prestigious employment. Thus, his qualifications include not only level of skill and any valued ascriptive factors but also the intensity of his own desire or motivation for high-level work.

We also assume that labor quality can be measured on a single dimension and that sons are susceptible to ordinal ranking in this respect. This means that the rank order of sons with respect to quality should fully correspond to the rank order of their occupational positions. We may illustrate this with two sons and three positions, viz., physician, attorney and dentist. Both sons are highly talented, responsible and ambitious, and both perceive the value of occupations in the same way. Thus, if recruits were needed in all positions both would become doctors; if this option were closed, both would become lawyers; and if neither of these options were open, both would become dentists. In other words, the same rule of labor substitution applies to both sons. Suppose, alternatively, that this rule applies to just one son and that the other, if denied the opportunity to become a physician, will become a dentist rather than a lawyer. This could occur because the second son evaluates occupations differently than the first, because his verbal skills are weak relative to his other talents or simply because he prefers the work of a dentist over that of an attorney. In any case, the two sons do not scale in the same

way. In this example, the two sons are not susceptible to the same ordinal ranking and a single rule of substitution does not apply for both of them.

The counter-example describes a quite realistic situation and, thus, the assumption of a single rule of substitution is not expected fully to reflect actual recruitment procedures. On the other hand, it is reasonable to expect that a single rule will dominate the recruitment process. In this regard, it should be noted that research results show a broad population consensus on the prestige ranking of occupations and a widespread preference for working in the more prestigious jobs. Also, insofar as jobs are rated highly, they typically are allocated to persons with strong educational and vocational training and, in some measure, to persons with positively valued ascriptive characteristics. It is also of interest that the "functionalist" notion, *viz.*, that the reward system operates to insure that the most qualified persons will occupy the most important positions is quite consistent with the rule we propose. Finally, we would strain credibility if we pressed the counter-example. It would be a rare son who, denied the option of becoming a physician but having at hand the opportunity of becoming lawyer or dentist, would wind up as an office clerk. Thus, it is our expectation that a single rule of substitution, while an incomplete representation of reality, will serve as a strong first approximation to the complex process of labor allocation.

If the set of destination classes of a standard mobility table represent ordinal groupings with respect to the rule of substitution, it is possible, given assumptions regarding the general distribution of labor quality, to obtain the specific distributions of labor quality for sons of each origin class. The comparison of these within-class distributions provides a description of the competitive standing of sons of differing origins. These distributions are, under the present formulation, the basis of labor allocation but stand prior to any specific allocation. In other words, these distributions are not determined by the marginals. Our purpose is to extract these within-class dis-

tributions of labor quality from national mobility tables and thus draw inferences as to the manner and degree in which a son's origins affect his chances in job competition. We begin with a formal description of the recruitment process and proceed to illustrate the manner in which variation in marginal distributions affects labor allocation. We next will describe an operational method for identifying within-class densities of labor quality. The paper concludes with an empirical application.

The Structure of Status Attainment

If quality is measured on a single dimension, there is a number, x , associated with each son such that the value of x is related to the summary value of his status-related advantages. The density function for sons of the i^{th} origin class is defined as $f_i(x)$ so that $f_i(x)dx$ is the proportion of sons of the i^{th} origin class with status-related advantages valued at x to $x + dx$. Figure 1 is a hypothetical representation of the densities of three origin classes. The graph of the first origin class, $f_1(x)$, is weighted to the right of those of the other two classes, indicating that these sons are relatively advantaged. The graph of the third class, $f_3(x)$, is furthest to the left, so that the average value of labor quality is intermediate in the second class and lowest in the third. Also, the relative peakedness of these densities indicates that sons of the first origin class are the least dispersed and that sons of the third social class are the most dispersed over values of labor quality:

If sons of these three origin classes are to be allocated over ordered destination classes on the basis of quality, each son allocated to the highest ranked class will exceed in quality every son not allocated to that class. Insofar as quality follows a continuous scale, ties will not occur and we will be able to define a value of quality, say x_1 , so that all sons with values above x_1 are in the highest social class and all sons with values below x_1 are in lower ranked classes. Moreover, this number will approach a unique value insofar as the origin class is large. If α is the upper bound of labor quality, the area under any curve lying to the right of x_1 , *viz.*,

Figure 1. Hypothetical Densities of Status-Related Advantages in Three Social Classes

$$F_1(x_{1,\alpha}) = \int_{x_1}^{\alpha} f_1(x) dx, \quad (1)$$

will be equal to the probability that a son of the specified origin class will attain a position in the highest destination class. Also, if N^0_i is the number of sons of the i^{th} origin class, there will be $N^0_i F_1(x_{1,\alpha})$ sons of this class in the preferred destination class. Finally, the total number of sons attaining positions in the highest class will be

$$N^D_1 = \sum_{i=1}^k N^0_i F_1(x_{1,\alpha}), \quad (2)$$

if k is the number of origin classes. Given the marginal values, N^0_i and N^D_1 , and given the within-class densities of labor quality, $f_i(x)$, the specification of the numbers and proportions of each origin class who enter the highest destination class is

contained in the specification of x_1 . Since the functions $F_1(x_{1,\alpha})$ are monotonically decreasing functions of x_1 and since N^D_1 is a weighted sum of the set, $F_1(x_{1,\alpha})$, N^D_1 is itself a monotonically decreasing function of x_1 . Thus if $f_i(x)$ is continuous and the origin classes are large, a unique value x_1 will fulfill equation (2).

As an illustration of this relation, suppose labor quality in the three social classes is distributed as in Figure 1 and that each origin class contains 1000 sons. In addition, we presume that the market is static so that 1000 sons are to be recruited to the highest ranked class. If we pick as a trial value $x^*_1 = .63$, the area under the first curve, $N^0_1 F_1(.63, 1.00)$, will be $1000 \times .352 = 352$, indicating that 352 sons of this class will enter the highest origin class. Also, $N^0_2 F_2(.63, 1.00) = 272$ and $N^0_3 F_3(.63, 1.00) = 99$, so that substitution on the right hand side of equation 2 yields

$$355 + 272 + 99 = 726,$$

which is lower than the true value of N^D_1 . If we choose $x^*_1 = .58$, we obtain $N^0_1 F_1(.58, 1.00) = 597$, $N^0_2 F_2(.58, 1.00) = 473$ and $N^0_3 F_3(.58, 1.00) = 213$, and these add to 1283 which is too high. If we select $x_1 = .604$, the relation is fulfilled exactly with 477 sons of the first origin class, 72 sons of the second class and 151 sons of the third origin class obtaining positions in the highest destination class. While these numbers add to 1000, those obtained setting x^*_1 above .604 will always sum to a number smaller than 1000 and those obtained setting x^*_1 lower than .604 will always sum to a number larger than 1000. Thus, .604 is a unique solution of x_1 . Finally, taking the marginal distributions as given, the allocation of 477, 372 and 151 sons of the first, second and third origin classes, respectively, to the highest destination class is the only allocation consistent with the hypothesized densities of labor quality. The cutting point for recruitment to the highest social class might be indicated in Figure 1 by dropping a vertical bar at .604.

Recruitment to each successive ranked class follows a similar logic. Thus, if x_1 is the cutting point for the highest destination class, all sons recruited to the second highest class will have status related advantages valued less than x_1 . Also, any son recruited to the second ranked class will exceed in value any son recruited to lower ranked classes. We can, therefore, find a number, x_2 , separating the second and third class so that x_2 fulfills the relation

$$N^D_2 = \sum_{i=0}^k N^0_i F_i(x_2, x_1), \quad (3)$$

where $F_i(x_2, x_1) = \int_{x_2}^{x_1} f_i(x) dx$ is the propor-

tion of the sons of the i^{th} origin class with status-related advantage valued between x_2 and x_1 and where N^D_2 is the total number of sons recruited to the second ranked social class. In the present example, x_1 is set at .604 and by iteration we find x_2 is located at .516, given $N^D_2 = 1000$ and that each origin class contains 1000 sons. This

implies that 370, 354 and 276 sons will be recruited to the second ranked destination class from the first, second and third origin class, respectively. More generally, we determine x_j , the lower bound of the j^{th} social class as the number fulfilling the relation

$$N^D_j = \sum_{i=1}^k N^0_i F_i(x_j, x_{j-1}), \quad (4)$$

given that the marginals, N^D_j and N^0_i , and the densities, $f_i(x)$, are known and that x_{j-1} is determined by solution of the preceding equation. Finally, if the number recruited to the lowest ranked social class is N^D_k , the number recruited to this class from the i^{th} origin class will be $N^0_i F_i(\beta, x_{k-1})$

$$= N^0_i \int_{\beta}^{x_{k-1}} f_i(x) dx \text{ if } \beta \text{ is the lower bound}$$

of labor quality. In fact, this number will be equal to the number of sons in the i^{th} class who were not recruited to higher classes. If, in the present example, we recognize three destination classes, there will be $N^0_1 F_1(\beta, x_{k-1}) = (1000 - 477 - 370) = 153$ sons of the first origin class recruited to the lowest ranked destination class. Proceeding in the same fashion, we have 274 sons of the second origin class and 573 sons of the third origin class recruited to the lowest ranked destination class.

Marginal Distributions and Patterns of Mobility

Under the present formulation, any specific mobility allocation depends not only on the within-class distributions of status-related advantages but on the numbers of sons originating in each social class and on current labor requirements. This is reflected in equations (2), (3), and (4) where the allocation is a function not only of the densities, $f_i(x)$, but of the marginal distributions, N^D_j and N^0_i , as well. Moreover, by varying the marginals, it is possible to construct allocations which seem to imply more or less equalitarian rules of labor allocation and which measure differently on standard indices of social mobility. Thus, it is possible to conclude for two populations which are similar in within-

class distribution of status-related advantages that one is more open or equalitarian than the other.

A few illustrations are sufficient to show the implications of marginal distributions for measured social mobility. Suppose that the within-class densities of status-related advantages are those displayed in Figure 1 and that, as in our initial illustration, there are 1000 sons in each of the three origin classes, but that we vary the example to reflect an upgrading of labor by allocating 1500 sons to the highest ranked destination class, and 1000 and 500 sons, respectively, to the middle and to the lowest ranked destination classes. Solving successively for

$$1500 = 1000 F_1(x_1, \alpha) + 1000 F_2(x_1, \alpha) + 1000 F_3(x_1, \alpha)$$

and for

$$1000 = 1000 F_1(x_2, x_1) + 1000 F_2(x_2, x_1) + 1000 F_3(x_2, x_1),$$

we obtain $x_1 = .562$ and $x_2 = .457$ and this implies the allocation shown in the middle panel of Table 1. The allocation implied under the initial illustration is shown for comparison in the upper panel of the table. If we use chi-square as an index of the degree to which the status of sons depends on the status of their fathers we obtain $\chi^2 = 509.6$ as against a value of 462.2 for the initial illustration. Also, Pearson's contingency coefficient takes on a value of .381 when labor needs are upgraded as against .365 when requirements are static. In addition, the fraction of sons who are mobile or whose situation is described by off-diagonal cells is 54.3% given upgrading and 53.2% for the static case. These considerations imply slightly more association between 'sons' and fathers' statuses and slightly more mobility in the case in which labor requirements are upgraded.

If we take a different tack and evaluate the amount of circulation mobility as a measure of the openness of the social structure, we find that there are 1129 moves under upgrading which occurred net of the 500 moves which are required to fulfill the marginals and that there are 1596 moves in the static case, none of which is needed to satisfy the marginals. Thus, only 37.6% of

Table 1. Labor Allocations under Three Sets of Marginal Distributions, Given Hypothetical Densities of Status-Related Advantages

Origin Class	Destination Class			
	I	II	III	Σ
I	477	370	153	1000
II	372	354	274	1000
III	151	267	573	1000
	1000	1000	1000	3000
	I	II	III	Σ
I	681	279	40	1000
II	550	340	110	1000
III	296	381	350	1000
	1500	1000	500	3000
	I	II	III	Σ
I	173	135	192	500
II	134	112	254	500
III	193	253	1554	2000
	500	500	2000	3000

sons "circulate" under upgrading as against 53.2% in the static case. Using these procedures, one might well conclude that the cross-tabulation in the middle panel of Table 1 describes a less open status structure than the cross-tabulation in the upper panel of the table.

If the status structure were bottom-heavy and static so that there were 500 sons in the first and second classes and 2000 in the third in both generations, measured mobility would fall. In this case, we obtain .562 and .457 for x_1 and x_2 , respectively, and this yields the allocation of the third panel of Table 3. Chi-square falls to 362.9 and the value of the contingency coefficient falls to .328. Also, only 38.7% of sons are mobile. Thus, this allocation would seem to describe a less fluid or less open population than that of the initial allocation. Finally, we will obtain varying results when we apply other standard measures such as mobility ratios to the three tables.

The Identification of the Densities of Status-Related Advantages

The preceding illustrations only confirm the well-appreciated fact that cross-population differences in the marginal distributions of origin and destination statuses introduce a measure of indeterminacy into

comparative statements relating to the openness or fluidity of class structures or to the degree and manner of dependence of a son's status on that of his father. In particular, we showed how measured mobility can vary even when the within-class densities of status-related advantages do not. However, there can be little satisfaction in this demonstration unless something can be said about the densities themselves. In other words, the theory of mobility outlined here will provide a structure for comparative statements about social mobility only if information relating to the within-class quality densities can be inferred from data.

A set of densities will fulfill the requirements of the model insofar as it preserves the ordering of status-related advantages across classes and a plurality of sets should approximate this condition. We are near to an operational solution if we assert that each density in the set is a member of some specified family of functions. This assertion will be reasonable to the extent that the set of curves described by the family is highly flexible since this will optimize the chances that it includes a set which closely preserves the between-class ordering of status-related advantages.

Let $\phi(x)$ be a family of functions, any member of which is uniquely identified by a set of parameters, $\theta_i = [\theta_{i1}, \theta_{i2}, \dots, \theta_{ip}]$. If the densities of status-related advantages are members of $\phi(x)$ for all classes, then any specific density, say $f_i(x)$, may be expressed as $\phi(x, \theta_i)$ which is to say that we know $f_i(x)$ if we know the associated vector, θ_i . Thus, if recruitment is based strictly on quality and if the family of functions which describe the within-class densities of quality is specified, the observed cross-classification of sons' and fathers' statuses can be expressed in terms of the marginal distribution of class origins and the parameters θ_i associated with each origin class. Stated explicitly, the observed cross-classification,

$$[N_{ij}] = \begin{bmatrix} N_{11} & N_{12} & \dots & N_{1k} \\ N_{21} & \dots & \dots & \dots \\ \vdots & & & \vdots \\ N_{k1} & \dots & \dots & N_{kk} \end{bmatrix}, \quad (5)$$

in which the element N_{ij} is the number of sons of the i^{th} origin status obtaining positions in the j^{th} ranked destination status, will, net of stochastic disturbances, correspond to

$$E[N_{ij}] = \begin{bmatrix} N^o_1 \Phi(x_1, \alpha, \theta_1) & N^o_1 \Phi(x_2, x_1, \theta_1) & \dots & N^o_1 \Phi(\beta, x_{k-1}, \theta_1) \\ N^o_2 \Phi(x_1, \alpha, \theta_2) & \dots & \dots & \vdots \\ \vdots & & & \vdots \\ N^o_k \Phi(x_1, \alpha, \theta_k) & \dots & \dots & N^o_k \Phi(\beta, x_{k-1}, \theta_k) \end{bmatrix}. \quad (6)$$

In this latter matrix, N^o_i is the number of sons originating in the i^{th} social class and

$$\begin{aligned} \Phi(x_j, x_{j-1}, \theta_i) &= \int_{x_j}^{x_{j-1}} \phi(x, \theta_i) dx \\ &= \int_{x_j}^{x_{j-1}} f_i(x) dx \end{aligned} \quad (7)$$

is the fraction of sons of the i^{th} origin class with status-related advantages valued between x_j and x_{j-1} . The cutting points are chosen to correspond to the boundaries of the destination classes so that $\Phi(x_j, x_{j-1}, \theta_i)$ is the expected proportion of sons of the i^{th} origin class who obtain positions in the j^{th} ranked destination class.

If p is the number of parameters required to identify $\phi(x)$, for each origin class, then $k \times p$ parameters must be estimated if the set $f_i(x)$ is to be recovered. In addition, the $k-1$ cutting points must be fixed to assure that the marginal distribution of destination statuses agrees with the data. Thus, the total number of equations needed for the estimation of parameters and for constraint of the marginals is $kp + k - 1$. If, as is typically the case, the matrix $[N_{ij}]$ is of full rank, it will yield $(k-1)^2$ linearly independent equations. Since $kp + k - 1$ is less than $(k-1)^2$ when p is less than or equal to $k-3$ and since this is not the case when p is greater than $k-3$, estimation

of the set $f_j(x)$ is operational if and only if p is less than $k-3$. Thus, we are allowed one parameter in a 4×4 table, two in a 5×5 table, and so forth.

These considerations indicate that the number of parameters needed for the identification of the members of the selected family of functions must be kept small if the model is to be operational for tables of modest dimensions. In other words, parsimony as well as flexibility must be taken into account in the specification of a family of curves. Balancing these needs, we have chosen the beta family. Members of this class of curves are identified by two parameters so that estimation of the set, $f_i(x)$, is possible when at least five status categories are recognized. Also, the functions included in the family are quite varied and can be U-shaped, an inverted U-shape, J-shaped or flat. The density of the beta function is

$$\phi(x, a, b) = \frac{x^a(1-x)^b}{\int_0^1 x^a(1-x)^b dx}, 0 \leq x \leq 1 \quad (8)$$

where a and b are the parameters which identify members of the family. Thus, for a specific within-class density we write

$$f_i(x) = \phi(x, a_i, b_i) = \frac{x^{a_i}(1-x)^{b_i}}{\int_0^1 x^{a_i}(1-x)^{b_i} dx}, \quad (9)$$

and for the expected proportion of sons of the i^{th} origin status with positions in the j^{th} ranked destination status we have

$$\begin{aligned} F_i(x_j, x_{j-1}) &= \Phi(x_j, x_{j-1}, a_i, b_i) \\ &= \frac{\int_{x_{j-1}}^{x_j} x^{a_i}(1-x)^{b_i} dx}{\int_0^1 x^{a_i}(1-x)^{b_i} dx}. \end{aligned} \quad (10)$$

The likelihood of obtaining the observed cross-classification of origin and destination statuses given the marginal distribution of origins, specified cutting points x_j , and specified pairs of parameters a_i and b_i for a table of k dimensions is

$$\begin{aligned} L &= \prod_{j=1}^k \prod_{i=1}^k [\Phi(x_j, x_{j-1}, a_i, b_i)]^{N_{ij}} \\ &= \prod_{j=1}^k \prod_{i=1}^k \left[\frac{\int_{x_{j-1}}^{x_j} x^{a_i}(1-x)^{b_i} dx}{\int_0^1 x^{a_i}(1-x)^{b_i} dx} \right]^{N_{ij}} \end{aligned} \quad (11)$$

Taking derivatives of the logarithm of L with respect to each a_i and each b_i and setting the resulting expressions equal to zero, we obtain expressions in which the a_i and b_i are the values most likely to give rise to the observed outcome. Specifically, we have k equations of the form

$$\begin{aligned} \frac{\partial \ln L}{\partial a_i} &= \sum_j N_{ij} \left[\frac{\int_{x_{j-1}}^{x_j} (\ln x) x^{a_i}(1-x)^{b_i} dx}{\int_{x_{j-1}}^{x_j} x^{a_i}(1-x)^{b_i} dx} \right] \\ &\quad - N_{0i} \left[\frac{\int_0^1 (\ln x) x^{a_i}(1-x)^{b_i} dx}{\int_0^1 x^{a_i}(1-x)^{b_i} dx} \right] = 0 \end{aligned} \quad (12)$$

and k equations of the form

$$\begin{aligned} \frac{\partial \ln L}{\partial b_i} &= \sum_j N_{ij} \left[\frac{\int_{x_{j-1}}^{x_j} (\ln(1-x)) x^{a_i}(1-x)^{b_i} dx}{\int_{x_{j-1}}^{x_j} x^{a_i}(1-x)^{b_i} dx} \right] \\ &\quad - N_{0i} \left[\frac{\int_0^1 (\ln(1-x)) x^{a_i}(1-x)^{b_i} dx}{\int_0^1 x^{a_i}(1-x)^{b_i} dx} \right] = 0. \end{aligned} \quad (13)$$

The marginal distribution of origin statuses is accounted for explicitly in equations of forms (12) and (13) but the marginal distribution of destination statuses is taken account only insofar as the cutting points, x_j , are accurately specified. To obtain values of x_j which are consistent with the marginals we fix the constraints

$$\sum_i N_{ij} \Phi(x_j, x_{j-1}, a_i, b_i) = \sum_i N_{ij} \left[\int_{x_j}^{x_{j-1}} x^{a_i-1} (1-x)^{b_i-1} dx / \int_0^1 x^{a_i-1} (1-x)^{b_i-1} dx \right] = N_{ij}^D, \quad (14)$$

which is to say we constrain the expected cell entries to agree with the observed column sums. There are $k-1$ cutting points or values of x_j and so $k-1$ equations of form (14) are needed. Thus, one among the k possible equations of this form is redundant and is, therefore, not used in the estimation.

We now have $2k + (k-1)$ equations for the identification of $2k$ parameters and $k-1$ cutting points so that a unique solution will exist if matrix of observed values is of full rank. However, analytic solutions for the desired values cannot be written in closed form and numerical methods therefore are required. A quadrature routine was adapted to the present system of equations and yielded the results we will report. In some preliminary results, the marginal distribution of destination statuses implied by the estimated x_j 's deviated modestly from the observed distribution. A doubling of the penalties associated with deviations from the equations of form (14) reduced the discrepancies to small proportions. The routine converges on the same solution when the trial values of a_i , b_i and x_j are varied and convergence is reasonably swift, given the dimensions of the system. Also, the residual error or lack of fit of the estimated values to the equations is very small.

Finally, it should be noted that these estimation procedures are based on asymptotic considerations and, thus, are appropriate only insofar as sample size is large. From an analytic point of view, the data are joint order statistics of the k origin populations. The development of estimation procedures appropriate to small samples would be a most tedious process and it is unlikely that the resulting formulation would be operational except at great cost. Considerations of cost also have dictated that we neglect the sampling distributions of the estimated parameters. Thus, any statistical analysis of the results is necessarily

limited to summary methods such as χ^2 tests of goodness of fit. In general, it is best to apply the model to large samples and to interpret the results deterministically.

An Evaluation of the Fit of the Model

A cross-classification of sons' and fathers' statuses in post-war Britain is provided by Glass (1954). Five origin and destination classes are recognized and the set of occupational categories were intended to represent ordinal classes. Thus, the requirements for application of the method are met.

The observed cross-classification is shown in the upper panel of Table 2. Appearing above and to the right of these numbers and set in brackets, we have the expected values or the elements of the solution for $E[N_{ij}]$ under the assumption that the within-class densities of labor quality are members of the beta family. A comparison of the observed and expected values provides a general description of the fit of the model. In general, the expected values reproduce the original table rather well. Thus 97.1% of sons are correctly classified under the expected allocation, which is to say only 99.9 sons or 2.9% of the total would have to be reallocated in order to reproduce the observed cross-tabulation exactly. On the other hand, the lack of fit cannot be assigned to randomness. Of the sixteen degrees of freedom of the original table, fourteen were spent in estimation, so that two remain for testing. The chi-square for goodness of fit is 41.8, and this means that the notion that randomness accounts for the discrepancy of observed and expected values cannot be seriously entertained.

It should be recalled that this model is offered as a first approximation to the recruitment process and not as a complete representation of it. Thus, non-random deviations from the expected pattern, while identifying limitations of the model, do not necessarily indicate rejection of it. Moreover, the pattern of deviations can provide us with additional information by suggesting other significant dimensions of the recruitment process. It is of interest in this connection that 58.4 of the 99.9 misplaced cases involve a shortfall in the assignment

Table 2. Observed and Expected Cross-Classifications of Statuses for British and Danish Sons*

Origin Status	Destination Status					
	British Sons					Σ
	1	2	3	4	5

* Expected cross-classifications in brackets.

of sons to diagonal cells. This suggests a principle of class inheritance whereby there is a tendency, net of the broad considerations of labor quality, for sons to take jobs similar in kind to those held by their fathers. The presence of such a rule is testified to in much of the literature and we are neither surprised nor dismayed to observe its influence here.

We obtain an indication of how the pattern of deviations stands with the effects of status inheritance taken into account if we adjust the diagonals to the observed values and proportionately reduce the other expected values in each row to make up the difference. The value of χ^2 in the adjusted table stands at 27.8 with 20.0 points due directly to four cells in the lower left-hand

corner of the table. Specifically, the expectation involves the allocation of too many sons of origin classes three and four to the highest destination class and the assignment of too few sons of origin class five to the two highest destination classes. It is of interest that these errors occur at the extreme tails of the densities of these three origin classes, involving only the upper 2% of sons of classes three and four and the upper 5% of class five. This pattern arises in other applications and it possibly reflects limitations in the flexibility of the beta density near its tails. If this is the case, it implies that, insofar as the beta function fails to fit the data, the errors will be felt differentially at the extremes of the distribution. From a practical point of view, this

means that substantive inferences relative to the distribution of labor quality will be weak to the extent that they are based on the extremes of the estimated densities.

The lower panel of Table 2 shows the observed and expected cross-classification of Danish sons (Svalastoga, 1959). The χ^2 statistic for goodness of fit is 31.8 and so the deviations are not accounted for by random error. The smaller χ^2 statistic can be explained since the size of the Danish sample is smaller than that for British sons. A rough index of the seriousness of non-random error, taking account of sample size, is the ratio χ^2/N . The value of the ratio is .014 for the Danish table and .012 for the British table, indicating that systematic errors of fit are present to approximately the same degree in both cases. To obtain agreement between the observed and expected values of the Danish table, it would be necessary to reallocate 4.8% of the sons. The fact that this proportion is greater than that observed in the British table can be largely explained by the difference in sample sizes. The bulk of the misplaced cases (75.7%) involves a shortfall of predictions on the diagonals and here, as in the British table, there are some serious discrepancies in the proportions at the extreme tails.

Social Mobility in Britain and Denmark

The occupational categories of the British and Danish tables are similarly defined and so it is reasonable to compare the two. The estimated within-class densities of labor quality of the five origin classes of British and Danish sons are displayed in Figure 2. Insofar as the relative quality of sons may be approximated by beta curves, this set of graphs provides a picture of the way in which a son's origins affect his chances of occupational attainment in the two societies. In addition, it should be noted that in both populations, the locations of the graphs are strictly ordered from right to left in descending order of the social rank of the origin class, an outcome which reflects the well-documented tendency of sons of high status origins to compete successfully for the more preferred occupational positions. We also note

that there is less overlap in the densities of the three highest classes in Britain than there is in Denmark, and this indicates that a British son's competitive advantage is more influenced by his father's position *within* the middle class than is the case for a Danish son. This result is consistent with Goodman's (1969) finding of discrepancies in the relations between sons' and fathers' statuses in the three upper classes of the two populations. Insofar as readers accept our formulation of the mobility process, the graphs of Figure 2 will provide them with a description of the nature of this discrepancy.

The simultaneous visual interpretation of ten graphs is cumbersome and can lead to confusion. Accordingly, we move to measures which extract the most important information relating to these densities. Some basic summary statistics are provided in Table 3. The parameters a_1 and b_1 , while of little interpretive use in themselves, may be used to construct the moments of the densities. For the mean and standard deviation, respectively, we have

$$\mu_1 = \frac{a_1 + 1}{a_1 + b_1 + 2} \quad \text{and}$$

$$\sigma_1 = \sqrt{\frac{(a_1 + 1)(b_1 + 1)}{(a_1 + b_1 + 2)^2(a_1 + b_1 + 3)}}.$$

If we take weighted averages of μ_1 and σ_1 , using the size of the origin classes as weights, obtaining $\bar{\mu}$ and $\bar{\sigma}$ and proceed to construct the "standard scores,"

$$z_1 = \frac{\mu_1 - \bar{\mu}}{\bar{\sigma}}$$

for the two populations, we have a one-dimensional scale of the location of the densities in terms of a common unit variance.

The standard scores, shown in Table 3, indicate a slightly greater range (2.41 *versus* 2.22 standard units) in the average quality of British as against Danish sons of the five origin classes. We also note that the highest origin class stands well above the others in Britain though not in Denmark, but that differences in the location of the three lower classes are greater in

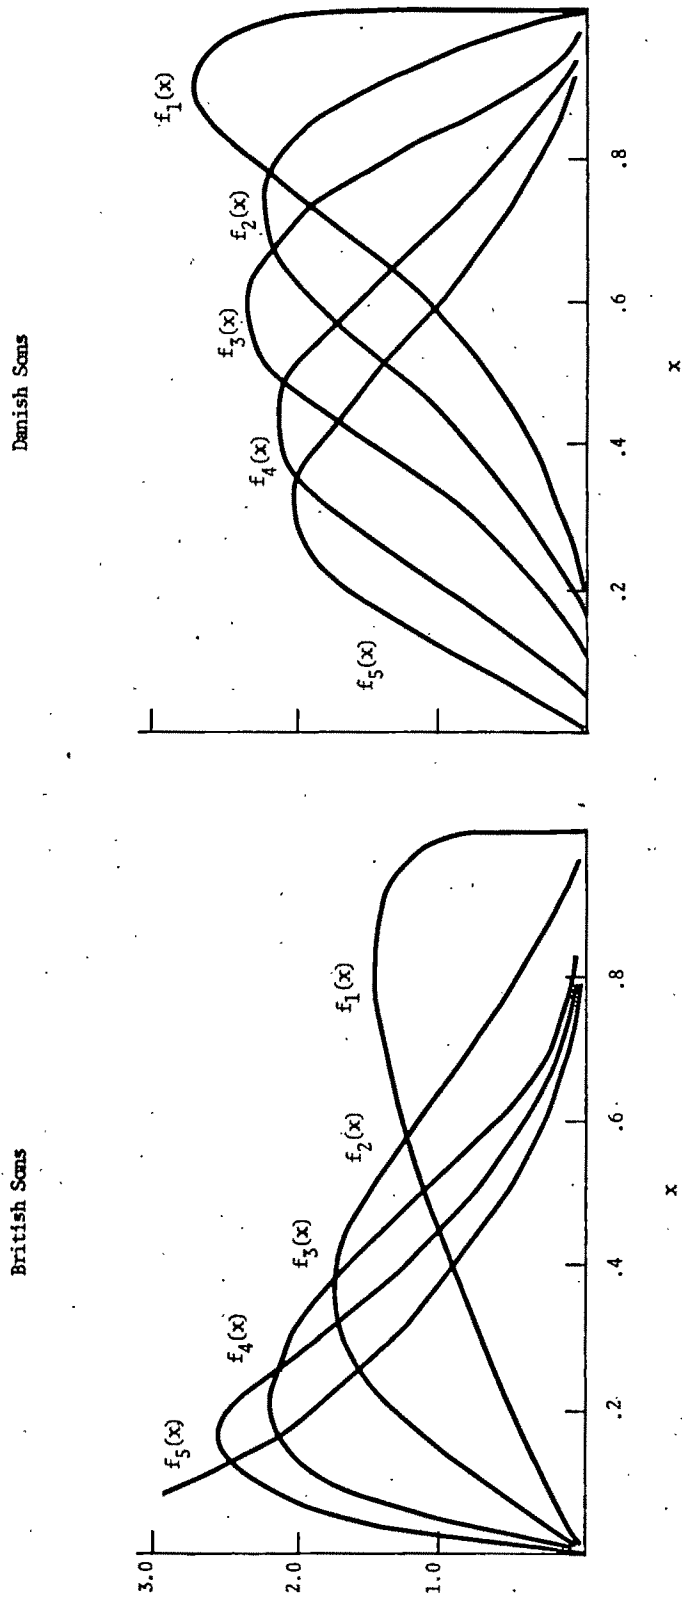

Figure 2. Estimated Within-Class Densities of Status-Related Advantages for British and Danish Sons

Table 3. Selected Parameters of the Within-Class Densities of Status-Related Advantages for British and Danish Sons

	British Sons Origin Status (i)					Danish Sons Origin Status (i)				
	1	2	3	4	5	1	2	3	4	5
Beta Parameters										
a_i	.82	.92	.83	.64	-.06	3.35	3.79	4.09	2.52	1.42
b_i	.14	1.75	3.11	3.87	2.86	.34	1.38	2.51	2.80	2.84
Derived Parameters										
μ_i	.615	.411	.308	.252	.196	.764	.668	.592	.481	.387

z_i	1.91	.74	.14	-.18	-.50	1.41	.85	.13	-.25	-.81
Pairwise Comparisons of Within-Class Densities										
Π_{11}		.734	.833	.878	.910		.672	.782	.878	.928
Π_{21}			.645	.725	.796			.634	.781	.867
Π_{31}				.593	.695				.681	.798
Π_{41}					.618					.647

Denmark than in Britain. Thus, while there is no great overall difference in the relative advantage of sons originating in the upper strata as against the lower strata of the two populations, a son's origins *within* the upper strata is of greater significance in Britain, whereas one's position *within* the lower strata is of greater significance in Denmark. Thus, if these rules of allocation operate in societies in which the larger number of sons derive from middle-class origins, the Danish rule will indicate more fluidity. If, as is in fact the case in both societies, sons are predominantly of lower-class origins, the British rule will imply less dependence of son's position on that of his father and, thus, greater fluidity.

The standard scores have the advantage of scaling the mean values of quality on a single dimension and of permitting comparisons to be expressed in a familiar statistical language. On the other hand, there is some coarseness to this approach in that the means are not taken from normal populations of similar variances as the procedure assumes. As a consequence, probabilistic statements based on normal theory cannot be made on the basis of these standard scores.

We have a simple summary measure which is free of this limitation if we consider the likelihood that a son from one specified origin class will exceed in quality a son of some other specified origin class. This measure is taken as

$$\Pi_{ij} = \int_0^1 f_j(x) \left[\int_x^1 f_i(x) dx \right] dx \quad (15)$$

and it may be calculated numerically if the densities, $f_i(x)$ and $f_j(x)$, are known. The measure requires no distributional assumptions and it is fully independent of the marginals. Also, since Π_{ij} is simply the probability that a son selected at random from the i^{th} origin class will exceed in quality a son selected at random from the j^{th} origin, it has clear substantive relevance.

Insofar as the estimated densities reflect the actual joint distribution of status-related advantages, the values of Π_{ij} furnish relatively refined information regarding the implications of social origins for occupa-

tional achievement. For example, the value of Π_{24} in the British table indicates that in Britain the probability that a son of the second origin class will exceed in quality a son of the fourth origin class is .725. The corresponding probability for Danish sons is .781. Thus, the advantage held by a son of class two over a son of class four is considerable in both populations and more strongly so in Denmark. An examination of the entries in these matrices indicates that the competitive advantages accruing to sons of the higher origin classes is substantial in both societies, with the likelihood that a son of a specified origin class will stand in a more favorable position than a son originating in the class just below—see the superdiagonal entries—being generally near two-thirds. Contrasting the extremes of origin status, we find that the probability that a son of the first origin class will exceed in quality a son of the lowest origin class to be .910 in Britain and .928 in Denmark. It should be noted that these advantages do not translate automatically into important differences in social position. Large differences in status occur when the status system is highly differentiated and, in general, differences in the characteristics of individuals in the society will not, in themselves, assure differentiation in the social system. In other words, status-related advantages will be parlayed into status itself only insofar as the requisite opportunities are available. However, in the comparison at hand, we have two highly differentiated societies in which the distribution of social rewards is strongly conditioned by occupational position.

A comparison of the two Π_{ij} matrices reveals that, in general, an entry in a particular cell of one matrix is near in value to the corresponding entry of the other matrix. Thus, there is no evidence of extreme differences in the populations in the distribution of status-related advantages between origin classes. On the other hand, there are some differences of sufficient numerical significance to warrant some comment. Taking comparisons among the three highest origin classes, we note that the implications of social origins for a son's

competitive standing are generally greater in Britain than in Denmark. This is due largely to the strong position of British sons of class one. Thus, Π_{12} and Π_{13} are .734 and .833, respectively, in Britain and they are .672 and .782 in Denmark. The discrepancy is small, however, with reference to the comparison of class two with class three, the value of Π_{23} being .645 for Britain and .634 for Denmark. A comparison of the three lower classes reveals that a son's origins here are of greater significance in Denmark than in Britain. Thus, the Danish values for Π_{34} , Π_{35} and Π_{45} all exceed the corresponding British values. In general, we find here, as we did in the comparison of standards scores, that origins within the upper classes are of greater significance in Britain whereas origins within the lower classes are of greater significance in Denmark.

The fit of the model to the data is imperfect, and so it is necessary to consider the implications of the deviations for the interpretation of these tables. In general, there are two factors which can account for the lack of fit. Thus, we will expect errors insofar as the beta family is not adequate to capturing the ordering of quality and we will expect errors to the extent that status-related advantages do not collapse to a single dimension. We will focus on the second of these factors because multidimensionality has important substantive implications and because there is evidence that it is present in those data.

Human mobility is a complex process involving a variety of motives and contingencies and it is, therefore, unlikely that any outcome will be fully accounted for in the rank value of sons and jobs. Thus, insofar as sons of a particular origin class have preferences and opportunities for a specific sort of work and these do not conform to the general ordering of jobs and labor quality, the assumptions of the present model will be violated and errors in fit should be anticipated. The existence of such effects does not undermine the basic thrust of our formulation, though it does indicate its limits. On the other hand, the present model has the advantage of providing a reasonable standard against which

one can test for the presence of other effects. As an example, consider the case of strict status inheritance. In both populations, the most obvious feature of the pattern of deviations is an excess of the observed over expected values in the diagonal cells. This suggests a tendency, net of considerations of quality, for sons to take on positions similar to those of their fathers. While this outcome is not surprising since status inheritance has been alluded to repeatedly in the analysis of mobility tables, the evidence of a strict affinity of sons' and fathers' statuses is more convincing when refracted through this model than it is in the context of most analyses.

Under typical procedures, ratios of the observed values in the diagonals to those expected under independence are constructed. Some measure of status inheritance is presumed to be present if, as is almost always the case, the ratios are in excess of unity. The weakness of this and other approaches based on a standard of statistical independence is that they contrast the outcome to the expectation which would hold if sons of all origin classes were similar with respect to their distributions of status-related advantages. If, as it is reasonable to assume and as our empirical results indicate, the quality of sons is positively related to the standing of their origin class, it will require no particular affinity of sons' and fathers' statuses for the observed diagonal values to exceed those expected under independence. Thus, in each of the three illustrative cases of Table 1, the "observed" diagonals exceed the expected values, though quality alone and not strict status inheritance is a consideration in the construction of the illustrations. On the other hand, the presence of strong positive deviations in the marginals, after considerations of quality are taken into account, as in Britain and Denmark, is evidence that the phenomenon of strict status inheritance is not spurious.

Structural Influences on Occupational Mobility

The relative competitive situations of sons of various origins is, under the present perspective, but one of two factors giving

rise to the mobility experience of a population. The outcome also is conditioned by the market within which competition takes place. Thus, as our introductory illustrations indicated, the marginal distributions of statuses in the two generations as well as the differential allocation of status-related advantages figure into the observed outcome. A quite similar distinction, viz., "structural" as against "exchange" mobility, is currently routine in the literature. Structural mobility is defined as the minimum number of interclass moves which must take place given the observed intergenerational shift in the composition of the labor force and operationally this is equivalent to the minimum number of sons who will be located off the diagonal if the marginals are to agree with the data. Exchange or pure mobility is simply the amount of mobility which is in excess of the structural component and it is measured as the difference in the sum of the off-diagonal values and the value of structural mobility (see Yasuda, 1964; Boudon, 1973: 17-39).

The classical formulation is not theoretically satisfying. Thus, structural mobility is defined as number of moves which would occur if mobility in the society were due to structural factors alone or if exchange mobility did not occur. If, as is always reported, there is mobility in excess of the structural component, some less radical rule of status inheritance must, in fact, be operating. Also, since exchange mobility is estimated by subtracting structural from observed mobility, it involves a mixing of the prevailing rule of allocation with an extreme standard. Accordingly, a logically consistent estimate of how much mobility was actually induced (or averted) by changes in the composition of the labor force and how much would have occurred under static conditions is not furnished under these procedures.

If an estimate of the operating rule of labor allocation is available, a meaningful evaluation of the amount of mobility induced by shifts in the occupational structure may be obtained by comparing the number of moves which occur in the face of the actual generational differences in labor force composition to the number of

moves that would be expected given the prevailing rule of allocation and a marginal distribution of sons' statuses similar to those of their fathers. In application, this involves moving the cutting points, x_j , to the positions which will yield a set of destination classes similar in size to the set of origin classes. The operational procedure here is the same as that described above in reference to illustrative cases.

The expected cross-classification corresponding to the static case is displayed in the left-hand panel of Table 4. The sum of the off-diagonal entries in Table 2 is 2097.4 and in Table 4 this sum is 2087.1. In other words, assuming the prevailing rule of labor allocation is described by the estimated within-class densities of labor quality, the net effect of differences in the class distributions of British sons and fathers is to place about ten sons in statuses other than their fathers'. Our estimate is subject to qualification in that the derived, rather than the observed, cross-classification of statuses is put forth as the estimated allocation associated with existing labor requirements. This is a consistent approach in that the same rule is used to generate the two allocations which are compared, but it is limited in that the effects, under varying labor needs, of factors not accounted for by the estimated densities are neglected. However, we see no convincing reason why these factors should be expected to have any strong systematic influence.

Our result contrasts sharply with the 192 moves of British sons which, under classical methods, would be attributed to structural changes. This relatively large number is mainly a result of the fact that these methods include in the structural component any move that shifting labor requirements would require, and among these there are many which would have taken place under static conditions. Somewhat less obvious, but equally relevant, are those moves which would take place in a static context but which do not occur in the context of actual labor needs. We have, for example, an expected 438.7 British sons of origin class five in other destination classes given the generational change in the class distribution and an expected 485.4 in other

Table 4. Expected Cross-Classifications of Statuses Given Static Distributions: British and Danish Sons

Origin Status	Destination Status				
	British Sons				
	1	2	3	4	5
1	53.2	39.0	15.0	18.4	3.4
2	47.1	146.5	97.8	165.3	38.1
3	11.0	90.2	96.9	240.0	80.0
4	11.0	156.4	225.1	753.7	363.8
5	6.7	62.8	83.2	332.6	359.6
	Danish Sons				
	1	2	3	4	5
	1	2	3	4	5
1	15.2	20.6	14.0	6.0	1.2
2	24.9	97.5	114.8	66.2	14.5
3	12.3	123.6	261.7	216.9	57.5
4	3.7	58.3	201.4	308.9	205.7
5	.9	17.9	80.1	179.9	251.1

destination classes under static conditions. Thus, excepting the case in which a strict caste rule is present, mitigated only by changing labor needs, the classical measure of structural mobility is likely to be a gross overestimate of the net number of status changes arising as a result of structural shifts.

The net effect of structural influences on the mobility of Danish sons appears to be trivial. The expected number of status changes given the differing labor force distributions of the two generations is 1419.0 and under static conditions the expected number is 1420.6. In other words, an expected *deficit* of 1.6 status changes occurred as a consequence of the dissimilarity in the occupational distributions of fathers and sons. By contrast, an application of classical methods leads to the assignment of 73 moves to the structural component.

Conclusion

A table of social mobility describes the outcome of an allocation process. The rules which govern the process are not described in the table and so any interpretive statements relating to the outcome will require assumptions about the nature of the allocation process. The model employed here assumes that sons may be rank ordered on a single dimension and that they are allocated over a series of ordered destination

classes on the basis of this ranking. The distribution of sons along this dimension is expected to vary according to origin class and, under the present formulation, these distributional differences account for the observed variation in the proportionate allocation over destination classes of sons of differing origins. An *a priori* specification of the nature of the within-class distributions is an operational requirement of the model. In the present application, these within-class densities are assumed to be members of the beta family. However, the basic conceptual framework does not depend on the choice of the beta family.

This model bears some similarity to that proposed by Levine (1972) in that both approaches treat the status categories of the table as intervals on a status continuum. Levine's approach differs from that presented here in that his allocation is oriented in terms of the distance between the statuses of fathers and sons. The cell values of his reconstructed table are developed in terms of the distance (on an underlying status continuum) of the cell from the diagonal and the constraints of the marginal distributions. He applies his model to Glass's (1954) mobility table and obtains an expected table which fits the data more closely than the reconstruction obtained under the procedures developed here. Goodman (1972) proposes a series of models which also fit these data well. His models, like that of Levine, accord special weight to the diagonal values and, in varying ways, they weight the other cells in terms of their distance from the diagonal.

The tendency of sons to hold positions similar in status to those of their fathers is a longstanding empirical generalization. Levine's model and those proposed by Goodman explicitly incorporate this phenomenon and so, to some degree, their formulations are post hoc. The present model does not incorporate a principle of status inheritance or take account of the distance between origin and destination

classes. Nonetheless, a quite respectable reproduction of observed mobility tables, including their diagonal elements, is obtained. This suggests that much observed status inheritance can be explained without recourse to a principle whereby sons have an affinity for statuses similar to their fathers. A model is powerful insofar as it can be disproved, and models which cater to the most striking features of observed data lack this property. In summary, our results indicate that much, though not all, of the observed tendency of sons to take on positions similar to those of their fathers can be explained without taking explicit account of this tendency in the modeling of the data.

SEX ROLES AND INTERPERSONAL BEHAVIOR IN TASK-ORIENTED GROUPS *

B. F. MEEKER
P. A. WEITZEL-O'NEILL

University of Maryland

American Sociological Review 1977, Vol. 42 (February):91-105

In the past, sociologists have proposed that men and women approach situations in which they have to work with other people differently; that men are "task" or "instrumental" specialists, while women are "social" or "expressive" specialists. Subsequent advances in research on the social psychology of small groups, on families, and on personality has largely removed the theoretical and empirical supports for this proposition. On the other hand, researchers continue to observe sex differences in behavior in a variety of task-oriented situations. This paper suggests that sex roles may be seen as the result of status processes. Since men have higher status than women, men are expected to be more competent than women and it is expected that competitive or dominating behavior is legitimate for men but not for women. Empirical studies of sex roles as related to task appropriateness, group problem solving, conflict, dominating behavior and role expectations are reviewed in support of this theory.

The subject of this paper is sex role expectations as they affect interpersonal behavior in task-oriented group situations. For a number of years, the prevailing theory in sociology was that men are "instrumental" or "task" specialists, and women are "expressive" or "social" specialists. This hypothesis, which has found its way into introductory and family sociology textbooks and which has been used *post hoc* to explain unpredicted sex differences in empirical research, was derived from the more general theory of interpersonal behavior of the Bales tradition of research on small groups (Bales, 1949; Parsons et al., 1953; Slater, 1955).

According to the general theory, task behavior (which is primarily in the "attempted answers" categories of the Bales coding system, suggestions, opinions and evaluations) and positive social behavior (primarily in the "positive reactions" categories, solidarity, tension release and agreement) are incompatible, but both are essential to a viable small group. Initially,

the theory was that it is difficult for one person (male or female) to engage heavily both in task and in social activities. Since both activities are necessary, a pattern of *role differentiation*, in which a group has one "task leader" with higher rates of task behavior than other group members, and a different "social leader," who has higher rates of positive social behavior than other group members, was hypothesized to be a universal feature of viable small groups.

The *sex role differentiation hypothesis* was derived from this more general role differentiation hypothesis (Bales and Slater, 1955; Zelditch, 1955). The reasoning was that, since families are small groups and all small groups have role differentiation, families must have role differentiation. Because of the biological factors of age and sex, fathers are best suited to be task leaders and mothers are best suited to be social leaders. Furthermore, the task/social distinction is a fundamental aspect of personality, established through socialization processes such as identification with same-sex parent and differentiation from opposite-sex parent.

The sex role differentiation hypothesis is appealing because (1) it is derived from more general principles of human behavior (role differentiation) and (2) it makes

* Theoretical and empirical research papers by several students have greatly aided our thinking on the subject of sex roles and interpersonal behavior, although they may not all agree with our conclusions. These students are: Denise Abrams, Sol Fulero, Tom Patterson, Gary Peck and Roger Reitman.

predictions for human behavior at several levels: personality, behavior in families, behavior in non-family groups, and entry into occupations (women enter "people-oriented" or "helping" professions). Subsequent research, however, provides little support for either the general principle of behavior or the specific predictions. After a brief review of research directly related to the sex role differentiation hypothesis, we will propose an alternative theory and review in more detail some research relevant to it.

Evidence on Role Differentiation: Incompatibility of Task and Social Behavior in Small Groups Generally

Attempts to test the hypothesis that task/social role differentiation is a universal property of small groups have shown that, by no means, do all apparently viable small groups have the expected differentiation pattern. Lewis (1972) and Bonacich and Lewis (1973) have concluded that the data from neither the original Bales studies nor from a number of more recent studies provide strong support for the idea that task and social roles are incompatible. Davis (1961) found that role differentiation was unrelated to the viability of a sample of discussion groups, and other researchers have concluded that the appearance of a role differentiation pattern is related to such factors as the degree of task orientation of the group members (Mann, 1961) and the legitimacy of task activities (Burke, 1967; Turk, 1961).¹

¹ Later work by Bales (1970) revised the notion that task and social behaviors are mutually contradictory dimensions of social behavior and suggested instead three orthogonal dimensions. One reason for the revision was the difficulty of reconciling two "functions" of the social leader, both of which were implied by the original formulation. On the one hand, the social leader was hypothesized to provide to the rest of the group the social rewards necessary to keep them feeling part of and committed to the group; this function emphasizes equalitarian interaction. On the other hand, the social leader supports the task leader in his directive and controlling activities and mediates between him and the rest of the group; this function emphasizes hierarchical, status-differentiating behavior. Discussions of sex role differ-

Several types of research based on theories and methods different from the Bales tradition have reached similar conclusions; that is, that the types of behavior or social structures that create social satisfaction are incompatible with the behaviors and group structures that lead to task performance under some conditions but are compatible under others. One such body of research is the study of communication networks (see, for example, Shaw, 1964; Glanzer and Glaser, 1961; Moore et al., 1972). Another is the work of Feidler and his associates on leadership style and group effectiveness (Feidler, 1964; 1967). Both of these areas of research suggest, as did the studies derived from Bales' work, that factors such as the demands of the task and the legitimacy of the group's status structure influence the degree of compatibility of task and social behaviors and the actual distribution of these behaviors in a small group.

Role Differentiation in Families

Research on families indicates that sex role differentiation is no more universal than role differentiation in general. In an early study, Zelditch (1955) had presented evidence from the Human Relations Area Files that sex role differentiation in families occurs in a significant number of cultures. Aronoff and Crano (1975), however, have concluded that cross-cultural evidence shows that, in a large number of subsistence economies, women contribute as much or more than men to family productive activities. This casts some doubt on the ubiquity of male task specialization in families. In studies of American families, Strodbeck (1958) and Kenkel (1957) have reported observing sex role differentiation, while Levinger (1964) and Leik (1963) did not. Leik's (1963) study also provides some insight into the relationship between family and non-family groups. He observed mothers of college-aged daughters to have low

entiation generally have assumed that it is the former aspect of social specialization that characterizes the feminine role; we argue that for most situations it is the latter.

rates of task behavior and high rates of positive social behavior when they were interacting with strangers (in both same-sex and mixed-sex groups) but high rates of both task and social behavior with their own families. March (1953) observed that the role differentiation in a set of married couples varied with the discussion topic. Heiss (1962) reported more sex role differentiation in pairs of strangers than in dating and engaged couples; as in Leik's (1963) experiment, this was because the women had higher rates of task behavior in the more intimate groups. In at least one study (Straus, 1967), fathers were observed to be predominant in both instrumental and expressive spheres.

In general, research literature on families (see, for example, reviews of literature by Collins and Raven, 1968; Waxler and Mishler, 1970) show that dominance, instrumental and expressive behaviors in families are often more variable than in other groups, depending on such things as the task, conditions under which the family is observed, situational factors such as sex of child present, and stage of family cycle. Rather than being, as many sociologists have assumed, the ideal place to study sex roles, families (at least contemporary American families) seem to be one of the worst places to get information about sex role expectations and behavior.

Sex Role Differentiation in Non-Family Groups

When we look for direct tests of the sex role differentiation hypothesis in groups other than families, we find that this hypothesis generally has been invoked *post hoc* to explain unpredicted sex differences rather than tested explicitly. In an early and influential study, Strodbeck and Mann (1956) had applied the task/social role differentiation hypothesis to sex roles in mock jury discussions. They observed that men were more likely to be highly active, to be chosen as valuable to the group by other members and to initiate acts in the attempted answers categories. Women jurors who were active were more likely than men to initiate acts in the positive reac-

tions categories. The Strodbeck and Mann data also showed that contributions by men were more valued than those by women (that is, being highly active was associated with being named as valuable for men, but not for women).

Most subsequent studies of the sex role differentiation hypothesis have dealt with families rather than with non-family groups. One exception is a paper by Eskilson and Wiley (1975), who tested a role differentiation hypothesis in *ad hoc* three-person groups of college students, with leaders selected by the experimenters. They reported no overall differences between men and women leaders in task contributions but higher levels of positive social behavior for women. They also reported that leadership behavior of men and women varied differently with the sex composition of the group and the rationale for selecting the leader (on the basis of competence or randomly). There is a large body of research literature not based directly on the sex role differentiation hypothesis but which also documents sex differences in task-oriented groups. Some of this research is examined later in this paper.

Sex Differences in Personality

A recent review of personality research on sex differences (Maccoby and Jacklin, 1974) concluded that many previously reported sex differences are not reliable; they appear in some studies and are contradicted by others. Maccoby and Jacklin have concluded (1974; chs. 6, 7) that girls generally do not seem to be more motivated toward "social" behavior than boys, nor less motivated to "instrumental" types of behavior. Existing empirical studies do not show girls to be reliably more sensitive to social cues, more dependent, more affiliative, more nurturant, more altruistic or more empathetic than boys. Maccoby and Jacklin (1974:149) have also noted that "males do not appear to have generally greater achievement motivation, although they may show more arousal of this motivation under directly competitive conditions. The task-orientation vs. person ori-

entation distinction seems to be a poor one from the standpoint of understanding achievement motivation of the two sexes."

A further problem with acquiring information about sex roles from personality studies is that the relationship between personality, as measured by verbal tests, and actual interpersonal behavior is often different for men and women. Many personality tests seem to predict behavior of men better than behavior of women. Some specific examples of personality characteristics that are reported to predict behavior for men but not for women include Machiavellianism (Christie and Geis, 1968), self-esteem (Eisen, 1972) and various "needs" as measured by the TAT (Sechrist, 1968). McGuire (1968:1166) has commented that "this finding of lower correlations for women than for men is not peculiar to the personality-influenceability area. Part of the lore of laborers in the experimental-personality vineyard is that if one wants to find strong relationships between personality variables and behavioral measures in college sophomores, one is wise to use male rather than female subjects."

Sex Differences in Occupational Choice

Occupational choices and the reasons for making them sometimes are given as support for the task/social sex role differentiation hypothesis. In fact, women have been found to be more people-oriented and less oriented to material rewards in the values they attach to occupations (Davis, 1963). However, patterns of occupational choice are affected by perceptions of the alternatives available, and the occupations available to women have generally been those with less reward in terms of money and prestige than those available to men. Also, many women have been able to consider the option of not working at all. Thus, the major reason for a woman to choose an occupation would logically be that she does value the rewards it has to offer, i.e., people-oriented activities rather than pay or prestige. There is evidence (Turner, 1964) that women who place a high value on material ambi-

tion expect to satisfy that ambition through their husbands' occupations, not their own. Among the Los Angeles high school girls who answered Turner's (1964) questionnaire, it was the ones who were materially ambitious but did not expect to work, not the career-oriented girls, who agreed with statements endorsing individualistic and instrumental behavior (for example, showing people how to argue intelligently versus trying to smooth over disagreements or trying to get a group to do things my way versus being quick to go along with group). Since occupational choices are made from among different sets of alternatives for men and women, it is difficult to use such choices, or the reasons for them, to infer different personality or value structures. The fact that persons faced with different sets of alternatives made different choices cannot be used as evidence either for or against the existence of different preferences.

It appears, then, that the dimension of task versus social orientation is no longer justified as an explanation of sex differences in behavior in task groups. In the first place, there is no evidence that social behavior and task behavior are universally incompatible, although there are some types of tasks and status structures for which this is true. In the second place, there is no reliable evidence that women are more motivated than men to maintain harmonious social relationships.

On the other hand, differences in behavior between men and women have been observed. Some of the sex differences that have been documented in the studies just cited include: higher rates of task behavior by men than women in some settings but not in others (Leik, 1963; March, 1953; Heiss, 1962); higher rates of positive social behavior by women when their rates of task behavior are comparable to those of men (Leik, 1963; Eskilson and Wiley, 1976); apparent lower evaluation of women's than of men's task contributions by women as well as men (Strodtbeck and Mann, 1956). The circumstances that were associated with high rates of task behavior by women included being with family or fiancé as opposed to being with

strangers (Leik, 1964; Heiss, 1962) and being appointed to a leadership position by an outside authority (the experimenter) (Eskilson and Wiley, 1975). We suggest that these as well as other research results (reviewed later) can be explained by a theory of status processes rather than task/social role differentiation. The theory comes from two sources: performance expectation theory and status consistency theory.

Status Characteristics and Expectation States Theory

This theory, presented by Berger, Cohen and Zelditch (1973) and Berger, Conner and Fisek (1974), proposes that the power and prestige order of a task-oriented group, as observed by differentiation of the distribution of participation, prestige and influence, is determined by initial differences in external status. The mechanism through which external status affects internal status is the establishment of performance expectations. When group members perceive that external status differences exist, the higher status person is, in the absence of information to the contrary, assumed by self and others to be more competent at the group's task. This means that his task contributions are more valuable than others' task contributions. If the group members want good task performance, they want the most valuable task contributions they can get. Thus, the person for whom they hold higher performance expectations gets more opportunities to participate, initiates more actions, receives more positive reactions and has more influence. The establishment of performance expectations on the basis of external status characteristics takes place even when the status characteristics are not previously associated with ability at the specific task. The process will not operate only if information is provided to, and accepted by all group members that the status characteristic is not relevant. This last proposition is referred to as the "burden of proof" assumption, because it says that a lower status person must prove competence while a higher status person need not. Carefully controlled experimental studies, using a variety of status char-

acteristics, provide support for the assumptions of the theory and various predictions derived from it (Berger et al., 1974). The hypothesis that, if information that a lower status person is competent is provided, performance expectations are established on that information rather than external status has also received support (Cohen and Roper, 1971; Freese and Cohen, 1973). The theory has been applied to sex as a status characteristic by Lockheed and Hall (1975), who concluded that sex does operate like other status characteristics—men having higher status than women.

For our purposes, these assumptions can be summarized in the following:

- Statement I—A. Group members for whom there are higher performance expectations will receive and take more opportunities to make task contributions, will have more influence and more prestige and will receive more expressions of agreement and approval than those for whom there are lower performance expectations.
- B. In the absence of information to the contrary, group members will assign performance expectations to self and others on the basis of external status characteristics.
- C. Sex is a status characteristic; males have higher status than females.

Certainly competence is one of the primary factors affecting the legitimacy of task contributions in a group. Other factors also related to external status may be hypothesized to be important. The second part of the theory deals with some of these.

Status, Competition, and Legitimacy

This part of the theory, unlike the expectation states model, is not drawn from a precisely formulated and experimentally tested theory. It comes from a variety of sociological theories involving social exchange, status, distributive justice, and legitimacy. We may first note that even in a cooperative task-oriented group, there is a mixture of competitive and cooperative

elements. When one individual makes a valuable task contribution, he or she is simultaneously helping the other group members toward a goal they value and enhancing his or her own power and prestige at the expense of the other group members. Blau (1964, especially chapters 3 and 5) has developed this argument from an exchange theory point of view. Kelley and Thibaut (1968) proposed a similar argument based on considerations of interpersonal trust and the attribution of intentions. That is, in deciding whether to accept and encourage task contributions by another person, group members must decide not only whether the contribution is valuable to the group, but whether it is motivated by cooperative (group) or competitive (individual status) considerations.² Kelley and Thibaut (1968:38-41) also have cited a number of empirical studies that show that task contributions are less accepted when they are, either in fact or as perceived by group members, motivated by desire for competitive status enhancement rather than the good of the group. Hollander and Julian (1970) have reported that (male) subjects will accept leadership from an incompetent person who shows a sincere interest in the group's activity, even though competence is the most important source of legitimate authority.

This argument is closely related to status consistency theory (Homans, 1961: ch. 12; Adams, 1965; Sampson, 1963; 1969) which suggests that, in addition to establishing performance expectations, external status characteristics establish the legitimacy or "justice" of the power and prestige structure of a group. Persons with high status outside the group "deserve" higher status within the group and are allowed to earn status by making contributions which are accepted by others. A person with low

status, however, who attempts to make task contributions may be assumed by other group members to be acting from motives of competitive status enhancement, which is not legitimate since he or she does not "deserve" higher status. Applying this to sex role expectations means that before task contributions from a woman are expected or accepted, there must be evidence either that she is cooperatively motivated or that it is legitimate for her to enhance her own status. For men, the role expectation is that competitive status enhancement is legitimate. We hypothesize that these expectations are held by both men and women, for both same-sex and mixed-sex settings.

This part of the theory can be summarized as follows:

- Statement II—A. In the absence of information to the contrary, a task contribution by one member of a task-oriented group which is accepted by others will be assumed by both self and others to raise the status of the contributor relative to the status of the others.
- B. (1) Raising one's own status relative to the status of others is legitimate for persons with high external status but not for those with low external status.
- (2) Since men have higher status than women, raising one's status relative to status of others within a small group is legitimate for men but not for women.
- C. The "information to the contrary" referred to in Statement II—A may be (1) information that a person is motivated to help others in the group rather than to raise his/her own status or (2) that the person legitimately has been assigned a higher status than others (for example, been appointed leader by an outside authority).
- D. Acts that will result in raising one's own status relative to others will be expected from persons for whom it is legitimate to raise their

² This is just as rational as taking task competence into account, since a person with good intentions, even though not competent, may be assumed to be willing to take suggestions from people who are competent and to distribute the rewards fairly. A person who is motivated by competitive status considerations, even though competent, would be likely to keep others from maximizing their rewards from the group effort.

status relative to others; such acts will not be expected or accepted from persons for whom it is not legitimate.

- E. These statements hold independently of performance expectations.

This, in combination with Statement I, suggests that women must prove that they are both competent and well-intentioned before either they or others expect or accept high levels of task behavior from them, whereas men need prove at most one of the two. Statement I will help to explain why women in many mixed-sex settings have lower rates of task activity than men, are less influential and are less often perceived as making valuable contributions when they do contribute. It also may help explain some of the higher rates of positive social activity of women, since one of the features of a power and prestige order is that lower status persons do more agreeing and expressing of approval relative to the number of task contributions they make than higher status persons (see, for example, Hurwitz et al., 1968; Lippit et al., 1958). It may be that the relatively high rates of positive social behavior that have been observed for women are also related to the necessity (Statement II—C(1)) of proving good intentions. Through providing expressions of approval, agreement and encouragement to others, women can prove that their task contributions are motivated by concern for the group and thereby legitimate task behavior.

This set of statements also will help explain why it is that women do not have lower rates of task behavior than men in all settings. If the external status characteristic of sex can be made to appear irrelevant to the task, or if the particular women involved can be made to appear competent, performance expectations will not be affected by sex. If, at the same time, high rates of task behavior are legitimated for women, sex differences should disappear.

Review of Some Empirical Research

The remainder of this paper presents a brief review of some of the many recent

empirical studies of sex differences in task-oriented group settings. Although many of these have been explained by some version of a task/social role differentiation model, most of them seem more consistent with differences in expectations for task competence and legitimacy of competition for status.

(1) *Sex appropriateness of task.* It may be suggested that women will be assumed to be more competent and put out more effort relative to men when working on tasks that are culturally defined as feminine: for example, cooking rather than cars. While there is some evidence for this (for example, Milton, 1959; March, 1953), we should also note that "feminine" activities generally are considered less prestigious than "masculine" activities. For example, a sample of college students, both male and female, who were studied by Spence and Helmreich (1972) expressed greater liking for a (hypothetical) girl who had masculine interests than one with feminine interests. Also, both men and women preferred a girl who was competent over one who was incompetent. Seyfried and Hendrick (1973) found a general preference for masculine role attitudes in a hypothetical person, male or female as well as a preference for a person who had sex-appropriate interests. These studies provide evidence that sex is a general status characteristic. They also suggest that varying the stereotyped sex-appropriateness of a task may not provide an adequate test of hypotheses relating status and sex, since the greater expected competence of women in feminine-appropriate tasks must be balanced against lower motivation of both men and women in these tasks due to lower prestige and expected reward from them.

Further insight into the effects of sex role expectations on expectations of task competence comes from some of the research reviewed by Maccoby and Jacklin (1974:154-6), which seems to indicate that females tend to express less confidence than males in their own future performance, even on tasks where females characteristically do as well or better than males or where subjects are using their own past performance as a standard.

(2) *Conformity*. Conformity or influenceability is a variable that has been studied extensively in task-oriented situations. When conformity is measured in the Asch situation and its relatives, females typically are reported to conform more than males (for reviews of this literature see Allen, 1965; McGuire, 1968). On the other hand, when conformity or influenceability is measured in a variety of other ways, these sex differences do not appear consistently (Maccoby and Jacklin, 1974:265-74). For both males and females, confidence in one's own ability at a task is related to low levels of conformity, and having high expectations for the ability of others is related to high levels of conformity (Cohen and Lee, 1975). It would appear that when women conform more than men, this is related to lower confidence in task abilities rather than higher motivation to be agreeable or to promote group harmony.

(3) *Group problem solving and motivation*. A number of studies of group problem solving have reported sex differences. Hoffman (1965), who reviewed this area of research, concluded that all-female groups generally do less well at problem solving than all-male groups but that sometimes mixed-sex groups are superior to either. He attributed the lower level of performance of all-female groups primarily to motivational differences, suggesting that males generally are highly motivated to solve problems and that females are not. Working with other females, he suggested, reinforced the women's rejection of the task while working with males increased their motivation and, hence, the amount of effort they expended. Mixed-sex groups were superior to all-male groups in cases in which competition between men in the all-male groups interfered with coordination.

Of particular interest is an experiment by Carey (1958) who measured male and female subjects' attitudes toward problem solving before and after a mixed-sex problem-solving effort, a discussion designed to instill positive motivation toward the task, and a second problem-solving session. The women's task performance improved after the discussion, but the men showed no

change. As Statement II suggests, in group problem-solving situations many women will not put out their maximum effort unless told to do so. Although men are more likely to put out maximum effort, the results may be competitive rather than cooperative.

(4) *Conflict studies*. Another body of research that documents sex differences in task-oriented situations comes from studies of conflict, coalition formation, and bargaining. Vinacke (1959) compared male and female same-sex triads in a coalition experiment and concluded that the sexes showed the same general pattern in that the two weaker members of a triad tend to ally when they can overpower the stronger, but form few coalitions when they cannot win by joining forces. In addition, he reported a tendency for women to form coalitions when none is necessary, not to ally when it is rational to do so, to form triple alliances, and to divide the prize equally. Uesugi and Vinacke (1962) reported that this "feminine" strategy is enhanced when the game is given a female-appropriate content and explained it as a result of women's greater "social" orientation. Caplow (1968:31-4), however, has shown that the conclusion of both studies that there is a "feminine" strategy is invalid, since the supporting data presented do not show statistically significant differences. The women's behavior in these studies is similar to behavior of men in other coalition studies in which the subjects turned out to be confused about the rules and conditions of the game.

Bartos (1970) reviewed several studies of negotiation behavior. He concluded that men were "tougher" negotiators than women; that is, men made fewer concessions and more demands. Subjects generally were tougher when negotiating against women than against men. In addition to being male, the "tough" negotiators tended to be young, of minority race and "poorly adjusted" as measured by the California Psychological Inventory.

Two-person, mixed-motive games, in particular the Prisoner's Dilemma, have been studied intensively for several years, and sex is one of the variables that has

been used in combination with others. In a Prisoner's Dilemma experiment, each member of a pair of subjects is presented with a choice or series of choices between two alternatives. The Cooperative alternative, if chosen by both, results in mutual gain; the Defecting choice, if chosen by one when the other Cooperates, results in a large gain to the Defector and a large loss to the Cooperator. Mutual choice of Defection results in mutual loss. There is, thus, a constant temptation to Defect even though the result is not desirable to either person. In fact, subjects in these experiments do tend to "lock in" to the mutual loss pattern. The usual dependent variable is described as the number of cooperative choices, although there may be other motives than a desire to cooperate or to compete behind the choices that a subject makes. It is the difficulty of attributing motivation to subjects in this situation that has made sex differences in mixed-motive games puzzling. In one of the earlier studies, Rapoport and Chammah (1965) found that female dyads consistently were more likely than males to lock in to the mutual defection pattern, which was interpreted as meaning that women were more competitive than men. While a number of later studies have replicated this, others have found the reverse or no sex differences. As the use of the Prisoner's Dilemma as an experimental paradigm developed, a number of variables were found to affect the level of "cooperation." Most of these seemed to produce an interaction with sex—variations tending to increase cooperation for one sex, but not the other. In general, women tend to be less "rational"; they respond less to act-by-act variations in choices made by the other person and are less accurate predictors of the other's behavior (e.g., Pilisuk et al., 1968). Women are also less likely to find and maintain an optimal strategy for maximizing their own rewards (e.g., Halpin et al., 1970) but are more responsive to other cues such as promises (Tedeschi, Powell, Lindskold and Gahagan, 1969; see also a review of a number of studies by Tedeschi, 1973) and attractiveness of the other subject (Kahn et al., 1971). Women have been found to be less

likely than men to maximize contributions to a group score even in a cooperative game in which neither person gains anything by not cooperating (Meeker, forthcoming; Meeker and Hornung, 1976). Women appear to be neither more competitive nor more cooperative than men.

Tedeschi, Shlenker and Bonoma (1973), reviewing a large number of conflict experiments, concluded that women are more extreme in bargaining behavior than men, responding more cooperatively to cooperation but more vindictively to exploitation. Terhune (1973), who reviewed essentially the same body of literature, suggested, as an explanation of the apparently less rational and more extreme behavior of women, the hypothesis that women tend to be more affiliative and dependent while men are more dominant and aggressive. Since coordination, directing and leading are dominance behaviors and are also skills necessary to achieve cooperation in the Prisoner's Dilemma, women are less likely to achieve cooperation. Withdrawal is a dependent behavior and, "in the Prisoner's Dilemma the only withdrawal possible is to the defection tactic which is usually interpreted as a conflict maneuver. It seems, consequently, that the greater conflict among women in Prisoner's Dilemma reflects not competitive orientations but, rather, less ability to establish coordination in a complex problem-solving situation" (Terhune, 1973:215). Translated from personality variables into status differences, this is consistent with Statement II; that is, women assume it is not legitimate for them to make task contributions.

The idea that the observed differences in the behavior of men and women in mixed-motive games are due to differences in willingness to take the initiative in a situation requiring coordination rather than differences in competitiveness or cooperativeness is supported by a series of experiments reported by Kelley et al (1965). In these experiments, subjects were presented with a situation that has a logical structure like a mixed-motive game but is not defined as a competitive situation. The subjects had to take turns pressing buttons to escape from a noxious stimulus; all could

escape only if efforts were properly coordinated. Women generally were less likely to escape than men, except that sex differences disappeared in a condition in which a signal of confidence ("I will wait for you") was used by a confederate. For both sexes, failure to escape was positively associated with (among other factors) an orientation toward taking cues from others rather than deciding independently. In this situation, as in the group problem-solving studies, the apparent reluctance of women to take the initiative disappeared when there was an explicit statement that such behavior was expected and acceptable.

The conflict studies are particularly relevant to Statement II, since the values of individual acts in these experiments are assigned by the experimenter. Thus, differences in behavior cannot be explained readily by differentiation of performance expectations. The results of the conflict studies seem consistent with the idea that the "feminine" role requires avoiding the kinds of behavior associated with competitive status enhancement or dominance, rather than with low level of interest in the task or with high motivation for equality, harmony or "helping" others. Some further insight into the dynamics of this in a two-person game setting is provided by Wiley (1973), who has reported that when same-sex and mixed-sex dyads were given a Prisoner's Dilemma type of task with no verbal communication there were no sex differences in cooperation. When verbal communication was allowed, the mixed-sex dyads had higher levels of cooperation than the same-sex dyads. This seemed due to the fact that, in all but one of the mixed-sex dyads with communication, the man suggested a mutual cooperative strategy which the woman then agreed to and followed, while neither the all-male nor the all-female dyads with communication were able to organize themselves. Once again, the women were observed to contribute to a group product only after someone else (in this case, the other subject) had asked them to contribute. As in the group problem-solving studies, this situation is one in which all-male and all-female groups

had more difficulty coordinating than mixed-sex groups.

This theory suggests that contributions to a task may be viewed as a type of competition because of their implications for distribution rewards. We should expect that when task contributions and rewards can be separated operationally, women should demand less reward than men for the same level of contribution. It already has been mentioned that studies of negotiation have found women demanding less than men. Another piece of evidence comes from a study by Leventhal and Lane (1970) who had college students work with a (fictitious) same-sex partner, told them that their performance was either superior or inferior to that of the partner, and allowed them to allocate a monetary reward. Men took more than half the reward when their performance was superior and somewhat less than half when it was inferior; women divided the reward equally when their performance was superior and took much less than half when their performance was inferior.

(5) *Dominating behavior.* A study by Megargee (1969) supports the assumption that women try to avoid *appearing* to "lead" or "dominate" others. This experiment examined the relationship between dominance, as measured by the California Psychological Inventory, and actual leadership behavior in dyads composed of one high-Dominance and one low-Dominance person. When the subjects must decide who is to be leader, the general pattern is for the high-Dominance person to suggest him or herself, and to be the leader. However, in the dyads with a high-Dominance female and a low-Dominance male, the usual pattern is for the high-Dominance females to suggest that the male be leader, to which he usually agrees.

There is some evidence that women find having influence less rewarding than men do. Gray et al. (1968) and Richardson et al. (1973) reported that in three-person same-sex groups whose task was to form words out of randomly appearing letters, the women's initiation of task behavior seemed to be less contingent on their having had influence on the others in the past.

These two sets of experiments also found that the women's acceptance of influence from others was less contingent on the value of the suggestions than that for men.

The theory also suggests that dominating or aggressive behavior will be more accepted from men than from women, regardless of competence. Wahrman and Pugh (1974) partially tested this by presenting male subjects with a confederate who violated procedural rules established by a group for a problem-solving task. The confederate was also made to appear competent or incompetent at the task. The subjects accepted influence attempts by nonconforming men whether competent or incompetent, although incompetence somewhat reduced the influence. The competent nonconforming female had somewhat less influence than the competent nonconforming male, but the incompetent nonconforming female had virtually no influence. Apparently, as our theory would predict, men will accept obnoxious behavior from other men whether competent or not, accept it to a certain extent from competent women, but not accept it at all from incompetent women.

(6) *General sex role expectations.* If, as we have assumed, differences in the legitimacy of competitive behavior are part of generally held sex role expectations, we should be able to find evidence for this in people's descriptions of ideal behavior. Although there is much speculation that stereotypes for sex roles are changing among American middle-class youth, Komarovsky (1973) reported that a sample of college men still endorsed the ideals of masculine assertiveness, determination, decisiveness, courage, independence and aggressiveness. Almost half of the sample expressed some anxiety over failure to live up to those ideals in their relationships with women. Evidence that there are cultural and social class differences in legitimacy of assertive types of task behavior for women is presented by Strodbeck (1951), who compared couples from three different cultures, and Tallman and Miller (1974), who compared middle- and working-class American families. The latter study also indicates, as we might expect

from our review of the problem-solving and conflict studies, that differences in the acceptability of task contributions from women are associated with differences in the ability of families to coordinate effectively for solving a problem.

Conclusions

This approach has been not to look for universal sex differences but, rather, to try to explain the differences between situations in which sex role differences appear and those in which they do not. The argument is that status rather than task/social differentiation is the crucial concept, as status affects performance expectations and expectations for legitimacy of competitive or dominating behavior. Information, accepted by self and other, that the females present are at least as competent as the males establishes one kind of situation in which sex differences in task behavior are minimized. Information, accepted by both self and other, that task behavior by the women is not motivated by competitive status enhancement or that competitive status enhancement is legitimate in this particular case establishes another situation. A review of the literature suggests some ways in which the latter kind of information may be conveyed. These include a woman's: (1) having high rates of social activity; (2) being appointed to a leadership position by an outsider, such as an experimenter; (3) being requested to make task contributions by other group members (4) delegating formal leadership to a male; (5) occupying a role in which leadership is expected (for example, mother *vis à vis* teenage daughter in American middle-class families); (6) working on a task that is defined as appropriate for women. Whether these have similar effects, the ways they relate to perceived task competence, their interaction with such variables as task legitimacy, and the similarity or dissimilarity of these processes to processes involving status characteristics other than sex are questions that might be addressed by future research. In particular, advances in theory and research on the relationship of social and expressive be-

havior to status processes would be helpful.

Finally, we might note that in predicting task-related types of behavior of men and women, one should keep in mind that although a review of research shows that there are some conditions under which the amount of task performance of women is inhibited compared to task behavior of men, there is evidence that sex differences in rates of task behavior are highly affected by situations. In many cases, the rates of women and men are approximately equal, and both women and men have been observed to change their behavior as the situation changes.

Research also shows instances in which, while groups of women had difficulty with a task because no one wanted to take the lead in coordinating activities, groups of men had difficulty with the same task because everyone tried to take the lead. As with other types of roles, the expectations people have for their own and others' behavior may either facilitate or hinder coordination. It appears that when either men or women in a task-oriented group operate according to stereotyped sex role expectations, they are more likely to hinder than to help coordination.

CONFLICT INTENSITY, MEDIA SENSITIVITY AND THE VALIDITY OF NEWSPAPER DATA*

DAVID SNYDER and WILLIAM R. KELLY

Indiana University

American Sociological Review 1977, Vol. 42 (February):105-123

Although quantitative studies increasingly dominate analyses of conflict, issues of data validity have received little consideration. However, in a recent article, Danzger (1975) shows that differential location of wire service offices across U.S. cities biases newspaper data on racial conflict frequency and concludes that other studies (particularly of racial disorders) which rely on news sources are similarly invalid. We challenge Danzger's treatment and develop an alternative model of validity (which is defined strictly as the probability that events will be reported; we do not deal with the accuracy of published characteristics of events). Our model specifies validity as a function of event intensity and media sensitivity, each of which is dependent on several indicated factors. Intensity determines the relative probabilities that different forms of conflict behavior will be reported. However, precise reporting probabilities also depend on media sensitivity to conflict events. This model indicates the conditions under which news reports are valid sources of conflict frequency data and generates hypotheses—including no bias in racial disorder studies—opposite Danzger's. We report findings from two separate analyses: (1) racial disorders across 673 cities from 1965 to 1969 and (2) largely nonviolent collective protests occurring in 43 U.S. cities during 1968. Both sets of results contradict Danzger's conclusions and support our event intensity-media sensitivity model of validity. We indicate how this model is useful for assessing validity in other analyses of conflict and suggest more general implications for treatments of bias in newspaper data.

Over the past decade, quantitative studies have come to dominate analyses of social conflict, particularly in the areas of collective protest and violence. Although some investigations of these phenomena focus on characteristics of individual participants (Rudé, 1964; Caplan and Paige, 1968) or protest groups (Gamson, 1975), most empirical inquiries analyze conflict events aggregated over spatial and temporal units. These latter studies include analyses of (a)

cross-national patterns of conflict, both domestic (Feierabend and Feierabend, 1966; Gurr, 1968; Hibbs, 1973) and international (Rummel, 1963; Tanter, 1966); (b) time series of collective violence and industrial strike activity within particular countries (Kirkham et al., 1970; Snyder and Tilly, 1972; Hibbs, 1974; Snyder, 1975); (c) subnational ecological units (Spilerman, 1970; 1971; Morgan and Clark, 1973; Eisinger, 1973; Chirot and Ragin, 1975).

* The Governmental Units Analysis data used here were provided by the Social Science Data and Program Library Service of the University of Wisconsin, Madison, and acquired with the financial assistance of the Political Science Research Laboratory and the Department of Sociology Quantitative Methods Training Program, Indiana University. We are also grateful to Russell Dynes of the Ohio State University's Disaster Research Center for sending us an otherwise unavailable Lemberg Center Report; to Peter Eisinger, University of Wisconsin, Madison, for generously giving us a copy of his U.S. city protest data;

and to Myra Brown, Mark Hayward and Steven Vandewater for research assistance. Interviews were conducted in November, 1975, with John Marlow and Bruce Cook, respectively, of the Associated Press and United Press International (Indianapolis) and with Richard Yoakam, Department of Journalism, Indiana University. We wish to thank Paula Hudis for comments on an earlier draft and Seymour Spilerman and the anonymous referees for suggestions which we have incorporated in this final version. None of the above persons or organizations is responsible for remaining errors.

Most of these attempts to isolate determinants of conflict and/or violence through ecological analyses of events rely on newspaper accounts as primary sources of data on episodes of the dependent variable. However, the assumption in such treatments, that news and other reports of events unobserved by the researcher adequately count and describe the behaviors of substantive interest, usually receives token if any consideration.¹

Such neglect of data quality issues is surprising in view of increasing evidence of bias in published news (White, 1950; Breed, 1955; 1958; Jacobs, 1967; Bagdikian, 1972; Tuchman, 1972; 1973; Sigelman, 1973; Molotch and Lester, 1974; 1975). More precisely, "bias" encompasses at least two discrete departures from some ideal standard of objectivity. One type concerns the *selection* of news, i.e., differential completeness of reporting across classes of events. Selection bears on validity in a statistical sense—the extent to which news derived data measure reporting practices instead of the desired population of events. A second form of bias is distortion in the *content* of news, including inaccurate reporting (Jacobs, 1967) and unbalanced interpretation of events (Bagdikian, 1972; Sigelman, 1973), which involves validity in a more closely journalistic sense. Although many treatments of media bias limit themselves to consideration of content issues (Bagdikian, 1972; Tuchman, 1972; 1973;

Sigelman, 1973), some address both types of validity (White, 1950; Breed, 1958; Molotch and Lester, 1974; 1975).² We stress this distinction between forms of bias because our substantive focus on conflict dictates a primary emphasis on *the probability that events are reported in newspaper sources*.³ Consequently, we restrict our analysis and use of the term "validity" to refer only to this type of bias.

Although analyses of conflict generally ignore work on media bias, in one recent paper Danzger (1975) challenges the validity of newspapers as sources of data on conflict events.⁴ Citing these other studies of biased news reporting as evidence, Danzger suggests that racial disturbances in the United States and reports of their occurrence in standard sources (*New York Times Index*, Congressional Quarterly's *Civil Disorder Chronology* and the Lemberg Center's *Riot Data Review*) do not conform to a straight line process of communication. Instead, he argues that the type of local reporting network—in particular, the pres-

² These studies all manifest a theoretical interest in the social construction of reality and account for bias in terms of the more or less subtle influences imposed by political inclinations of news gathering organizations and their personnel (Breed, 1955; Bagdikian, 1972; Sigelman, 1973), reporters' everyday job constraints (Tuchman, 1972; 1973) and/or broader loci of power in society (Breed, 1958; Molotch and Lester, 1974; 1975). Therefore, this approach is better suited, at least where overt censorship does not exist, to explain bias in the journalistic rather than in the statistical sense. Moreover, empirical evidence of journalistic bias is much stronger.

³ Some aggregate indices of conflict (e.g., numbers of participants) are based on the content of news reports. However, since every ecological study relies in part (and often solely) on frequency measures, this issue of counting accuracy involves more general implications for empirical analyses of conflict data. In addition, we suspect that substantial underreporting constitutes a larger component of error in content-based measures than does bias in the reports themselves.

⁴ We consider some general implications for treatments of media bias in our conclusions. However, the bulk of our discussion focuses heavily on Danzger's study because it directs hypotheses of bias explicitly to conflict and violence and, therefore, raises serious questions concerning previous empirical work in this entire substantive area.

¹ With few exceptions, e.g., archival checks in Tilly's (1968; 1975) French violence study, assertions of reporting validity, particularly in cross-national analyses, are based on zero-order correlations between measures of conflict and indices of press censorship (Gurr, 1968:1108n; Tanter, 1966:43-5). However, positive associations are not adequate evidence of validity for two reasons. First, since other determinants of conflict variation are not controlled, conflict may be reported less fully under conditions of press restrictions even if such places have greater mean levels. Second, such correlations do not address the following possibility. Assume a typical situation in which several measures of conflict are combined. Even though each indicator's validity may be constant across nations, summary scores will (assuming differential composition of event types by country) be biased to the extent that some measures are less completely reported than others.

ence of an Associated Press (AP) or United Press International (UPI) wire service office in a city—substantially increases the probability that accounts of an event will actually appear in the printed sources (especially the *Times Index*) used in ecological analyses. Consequently, the results of such analyses should be biased by variation across cities in these different reporting mechanisms.

Danzger's (1975:579) tests of this contamination hypothesis are based on regression analyses of "... 644 cities in the continental United States, having populations of 25,000 or more by the count of the 1960 U.S. Census." His operationalization of the dependent variable uses the *Times Index* reports of "... all conflict events, initiated from either side and by as few as one person, with the prime emphasis and concern being on civil rights demonstrations" (1975:571). Racial conflicts listed from 1955 to 1965 are aggregated over cities and regressed on number nonwhite, a South/non-South dummy variable, city age, number unemployed and an AP/UPI dummy variable.⁵ Since AP/UPI substantially increments the R^2 even after other factors are entered in stepwise regressions, Danzger concludes that reports of conflict events are indeed biased in the hypothesized fashion. However, absence of a wire service office will not necessarily lead to underreporting:

once the word gets out about a newsworthy story, the wire services ... will send their own teams of reporters to investigate the matter further. We therefore expect that if we compare cities with a "substantial" number of stories but without wire service offices to cities with wire service offices, we will find no difference in the number of conflicts reported. (Danzger, 1975:580)

This supplementary point is examined with

⁵ Danzger also includes a number of other control variables (e.g., numbers employed in public administration and educational service, foreign-born and foreign stock, employment in managerial occupations and a dummy variable for state capital cities), but finds these measures to be individually and cumulatively unimportant in explaining patterns of conflict or reducing the impact of AP/UPI. We exclude these additional indicators from our reported analyses.

analyses of 83 cities for which ten or more conflict events were reported. Danzger eliminates the association between AP/UPI and number of conflict reports by controlling for number nonwhite and a dummy variable for state capital cities and interprets these findings as support for the frequency-noncontamination hypothesis.

Although Danzger's definition of racial conflict is broad (more than ten thousand reported events qualified for his sample between 1955 and 1965), he takes the close correspondence between his previous results (Danzger, 1968) and those of studies (especially Spilerman, 1970) which examine spontaneous, collective racial violence during the 1960s to warrant the conclusion that analyses of racial violence (e.g., see also Downes, 1968; 1970; Jiobu, 1971; 1974; Lieberman and Silverman, 1965; Wanderer, 1969; McElroy and Singell, 1973) are similarly biased. Moreover, Danzger's (1975:573) criticisms are particularly serious in that he explicitly extends them to all investigations of conflict which ultimately depend on some wire service reporting mechanism.⁶

Danzger's raising of this largely neglected issue of validity in conflict data is welcome. However, his substantive treatment is misleading and seriously incomplete. Danzger mistakenly assumes that (given a particular type of communications network) all conflict events are homogeneous and, therefore, equally likely to be reported. Consequently, his model of validity considers that data contamination is solely a function of the reporting mechanism. As we later show, this shortcoming produces faulty empirical

⁶ Although the AP/UPI variable has a substantial net influence on conflict in Danzger's analyses, it does not alter the effects of major substantive importance (number nonwhite and Southern location). However, he properly suggests that other studies may not be so fortunate with respect to stability of conclusions after corrections for possible reporting biases. Moreover, Danzger's challenge of the validity of conflict analyses is potentially more serious than even he indicates. His criticisms logically apply not only to newspapers, but to all sources of conflict data in which media sensitivity (and, therefore, event-reporting probabilities) vary across temporal and spatial units.

predictions concerning the validity of other studies.

This is not to claim that all conflict data are unbiased—Danzger's own results dispute that hypothesis—but that the Danzger model does not provide a basis for discriminating between many valid studies versus those vitiated by reporting errors. In the present context, we develop an alternative model of validity as a function of the *interaction* between the *intensity* of conflict events and the *sensitivity* of reporting mechanisms (each of which is dependent on several specified factors). This alternative yields testable hypotheses concerning conditions under which events will be underreported. One such hypothesis is that data used in the analyses of collective racial violence, on which Danzger focuses criticism, are unbiased. As a partial test of our model versus Danzger's, we report analyses of data on (1) violent racial disorders across 673 U.S. cities from 1965 through 1969 and (2) collective protest events (racial disorders are explicitly excluded) occurring in 43 U.S. cities during 1968, from a study by Eisinger (1973). In both cases, the empirical findings provide strong support for our arguments and none for Danzger's. However, while these analyses focus on violence and protest in the urban U.S. during the 1960s, for reasons of data availability and direct relevance to Danzger's conclusions our treatment of these issues should be applicable to other times and places.

CONFLICT INTENSITY, MEDIA SENSITIVITY AND DATA VALIDITY

An overview of some longstanding issues in the definition and measurement of social conflict will aid us in developing certain central points in our interaction model of validity in conflict data. After discursive treatment of these issues, we present our arguments in more rigorous form.

Defining and Operationalizing Conflict

The proper definition and classification of "conflict" has long evidenced conceptual problems and disagreements (cf. Mack and Snyder, 1957; and especially Fink, 1968,

for an excellent review of such issues). For example, whether psychological antagonisms constitute an underlying determinant or conflict itself⁷ and whether conflict encompasses latent opposition of interests (competition) as well as manifest interactions are points of continuing definitional debate. Similar disputes occur in attempts to classify forms of conflict. Different schemes variously identify the social characteristics (as in racial or industrial conflict), level of complexity (individuals, organizations, states) or structural relations (intra- versus extrasystemic) of the parties involved as critical dimensions along which forms of conflict fundamentally differ (Fink, 1968).

All quantitative studies of conflict partially "resolve" these metatheoretical issues by restricting their analyses in necessary ways: i.e., to observable interactions, occurring at a specified level of analysis, and among parties with certain identifiable social or political characteristics (e.g., racial groups, national governments).⁸ Aside from these global limitations, however, empirical treatments employ either of two general strategies in their operationalization of conflict. The first of these is a "multiple-indicator" approach which assumes (a) the existence of some underlying dimension, which is substantively designated "conflict" (Rummel, 1963; Tanter, 1966; Danzger, 1975), "political instability" (Feierabend and Feierabend, 1966), "civil strife" (Gurr, 1968), etc. and (b) that combining (i.e., summing, usually after weighting) indicators of a variety of behavioral manifestations of conflict adequately captures the

⁷ In one extreme position on this issue, Shepard (1964) implies that psychological antagonisms constitute "conflict," whereas observable behaviors are merely forms of conflict resolution. Fink himself argues for a broad definition which includes both (unobservable) psychological hostilities and conflict behaviors.

⁸ The necessity of these strategic limitations in empirical analyses is admittedly obvious. Our point here (and throughout the paper) is that operational restrictions regularly involve sacrifices in generality *vis-à-vis* some widely held conceptions of conflict. We attempt to indicate the conditions under which accommodation to issues of data validity warrant these theoretical costs.

conflict or other specified theoretical variables. Although this multiple-indicator treatment is more easily recognized in studies which use factor analyses to weight conflict indicators (Rummel, 1963; Tanter, 1966), it also characterizes investigations (e.g., Danzger, 1975) which merely sum (i.e., weight equally) events of different form.⁹ Whatever the weighting technique, this approach assumes that different forms of conflict behavior are equally well measured and reflect similar causal processes—although there may be “substitution effects” among observed event types across time and space.

A second strategy for operationalizing conflict restricts empirical inquiry to relatively specific and uniform types of behavior (we label this the “form-specific” approach), such as industrial strike activity (Britt and Galle, 1972) or “instances of ‘spontaneous outbreaks’ . . . characterized by primarily Negro aggression” (Spilerman, 1971:427n). This form-specific approach considers that underlying causal processes vary across forms of conflict behavior (or that similarities should be verified rather than assumed). Moreover, studies in this line generally further limit phenomena under empirical investigation according to characteristics of events, such as minimum criteria of size, duration or violence. Examples of such operational boundaries are “thirty or more individuals” (Spilerman, 1970:630n, on racial disorders), “at least one group of fifty or more persons in the course of which someone seized or damaged persons or objects over resistance” (Snyder and Tilly, 1972:522, on collective violence in France) and “all strikes and lockouts which continue for 1 full day or shift or longer and . . . involve six workers or more” (U.S. Department of Labor, 1974:15, on its definition of work stoppages). Although these operational limitations are often imposed on theoretical

grounds,¹⁰ they almost always involve strategic assessments concerning equivalent “visibility” (probability of being reported) of all events which meet minimum criteria for inclusion.

In summary, these multiple-indicator and form-specific strategies differ in their assumptions concerning variation in causal processes across conflict behaviors.¹¹ Moreover, those who utilize the form-specific approach apparently are willing to sacrifice range of theoretical generalization for greater confidence that conclusions are adequately supported by the data. For example, there are no compelling reasons to treat racial disorders involving twenty persons or French collective violence with groups of forty participants as either definitionally or substantively different from those events which meet the minimum size criterion reported by Spilerman (1970) and Snyder and Tilly (1972). Consequently, attenuation of the range of conflict behavior to which results of these studies may be generalized is justified only if (a) various forms of conflict behavior have differential likelihoods of being reported and (b) the inclusion criteria employed effectively discriminate among these different levels of validity.

Although available evidence is sketchy, it suggests affirmative conclusions on both these points. For example, Tilly’s (1968) French violence study, which checked readings of two daily Paris newspapers against archival and secondary sources, indicates that violent disturbances meeting the size criterion were more likely to be (and were almost fully) reported. More important for

⁹ The “form” of conflict refers to (usually arbitrary) distinctions among event types according to their “contextual” features (e.g., social characteristics and/or complexity of involved parties, as in racial versus industrial and intra-versus international conflict).

¹⁰ For instance, “discontent” models of industrial conflict view individual absenteeism, sabotage, etc. and strike activity as indicators of the theoretical variable (e.g., Knowles, 1954). However, explanations which stress *organizational* mechanisms (Britt and Galle, 1972; Shorter and Tilly, 1974; Snyder, 1975) treat individual and collective protests as qualitatively different forms of industrial conflict.

¹¹ Space limitations preclude discussion of available evidence on such variation across forms of conflict. For good treatments of the causal assumptions implicit in various operational definitions of “conflict” and “violence,” see Nardin (1971), Jacobsen (1973) and Tilly (1975).

our inquiry, however, is to show that various forms of conflict behavior measured in multiple-indicator analyses have different reporting probabilities. For these purposes, we draw on two representative studies in this line (Feierabend and Feierabend, 1966; Danzger, 1975). In the Feierabends' (1966:251) cross-national investigation, "data on internal conflict behaviors were collected for eighty-four nations for a fifteen-year period, 1948-1962. The data derive from two sources: *Deadline Data on World Affairs* and the *Encyclopedia Britannica Yearbooks*." Some thirty conflict behaviors are included; these range in magnitude from exiles, arrests of a few insignificant persons and crisis within nongovernmental organizations to civil wars, *coups d'état* and mass arrests (Feierabend and Feierabend, 1966:255). It is likely that the latter set of event types is far more fully reported (for reasons of size, violence and "political significance") than the former set in these (as well as newspaper) sources. Moreover, underreporting of the less visible event types probably varies across units—i.e., a few arrests are less likely to be listed for Afghanistan than for the United States because of differences in international importance and locational proximity to the source compilers and consuming public. Although we consider these points highly plausible, we have independent evidence only in the following instance. Feierabend and Feierabend purport to include all strikes (though these are divided into "general," "macro" and "micro" strike categories) in their analyses. However, more strikes occurred in the United States alone during 1961 and 1962 combined (U.S. Department of Labor, 1974:368) than the total number of events of *all thirty types* in the Feierabends' data for 84 nations from 1948 through 1962. With these strike indicators, therefore, we can be certain of drastic underreporting bias. Moreover, it is extremely doubtful that such serious validity problems pertain to certain other measures (e.g., civil wars).

Analogous points may be raised concerning Danzger's racial conflict data, in which events "initiated from either side and by as few as one person," most of them

apparently nonviolent ("prime emphasis and concern . . . on civil rights demonstrations"), are included. Danzger does not explicitly define "conflict." However, if we take it to mean antagonistic interactions, then certain forms of racial conflict are subject to the same under- and differential reporting biases noted in the Feierabends' work. For example, Berk and Aldrich (1972) indicate that white retail merchants engage in a variety of antagonistic behaviors toward their black customers, and that such acts are apparently "meaningful" to ghetto residents because they help explain patterns of vandalism in civil disorders. It is at best unlikely that many of the large number of hostile merchant-customer interactions are reported for any city. To the extent that such events are listed in the *Times Index*, we agree that AP/UPI cities (especially New York) should be favored. Again, however, we doubt that larger and more violent conflicts (e.g., racial disorders) are subject to such underreporting (in fact, we suspect that disorders were equally well reported regardless of location in AP or UPI cities). Therefore, we challenge Danzger's argument that validity depends only on the reporting network. In the following section, we present a model of validity which depends *both* on reporting *and* the differential characteristics of conflict events indicated here.

Conflict Intensity and Media Sensitivity: An Interactive Model

We proceed from the final point developed above, that different forms of conflict behavior have differential probabilities of being reported in newspapers and other standard sources of event frequency data. We specify that these differential likelihoods vary positively with the *intensity* of conflict behavior. This intensity dimension is reflected (and operationally defined here) in three measurable characteristics of any observable conflict event: *size* (total number of persons ever participating), *violence* (extent of physical damage to persons and/or property) and *duration*.¹² Although these

¹² Although some analyses of conflict (e.g., Britt and Galle, 1972) make a distinction be-

components of intensity are empirically related (Snyder and Kelly, 1976), they are conceptually distinct and are expected to have partially independent (positive) effects on reporting. (We also recognize that other characteristics of conflict events, such as the nature of the participants, should affect reporting probabilities. However, these are not components of intensity and are considered subsequently.)

Therefore, given N discrete forms of conflict behavior (event types), E_1, E_2, \dots, E_n , and (hypothetical) information on their intensity components, we can (1) assign mean intensity scores, $\bar{I}_1, \bar{I}_2, \dots, \bar{I}_n$ to each and (2) *rank-order* each event type, $E_1 > E_2, \dots, E_{n-1} > E_n$, according to its greater or lesser likelihood of being reported. (For purposes of convenience, we will assume throughout that $\bar{I}_1 > \bar{I}_2, \dots, \bar{I}_{n-1} > \bar{I}_n$ and that intensity scores for each event type are normally distributed about their mean values.) We stress, however, that precise probabilities, $p(E_1), p(E_2), \dots, p(E_n)$, *cannot* be determined in the absence of information about the sensitivity of the reporting mechanism.

As Danziger (1975) shows, reporting mechanisms differ in their sensitivity to conflict events. We operationally define *media sensitivity* as the event intensity above

which the probability that conflicts will be reported exceeds a given criterion level (say .99). More sensitive media sources have lower thresholds and report larger ranges of conflict behaviors. Therefore, while the probability that an event type will be reported increases with its mean intensity, a given indicator of conflict behavior will achieve adequate validity only if the media source is sensitive enough to record at least 99 (or other arbitrary) percent of all occurrences. Moreover, where media sensitivity varies across spatial and/or temporal units of analysis (e.g., AP/UPI versus other cities; the U.S. versus Afghanistan in the Feierabends' study), conflict indicators are valid only if reporting for the *least* sensitive unit is greater than or equal to the specified criterion level.

Several corollary points, suggested in our earlier discussion, follow from this interactive model of validity in conflict data. First, given the sensitivity of newspaper and other standard sources, it is unlikely that *any* multiple-indicator analysis of conflict achieves adequate validity. These problems of biased data should be particularly serious in cross-national studies (Feierabend and Feierabend, 1966; Gurr, 1968; Hibbs, 1973; Rummel, 1963; Tanter, 1966), which analyze events of widely varying mean intensities *and* units (countries) across which media sensitivity differs considerably. Second, form-specific strategies for operationalizing conflict are more likely to be valid, particularly when the minimum inclusion criteria are set at relatively high levels of intensity (e.g., Spilerman, 1970; 1971). However, since most form-specific studies lack independent confirmation concerning validity, it remains plausible that their indicators of conflict behavior are, in some cases, partially contaminated and, in others, entirely valid but unnecessarily restrictive. In general, we specify that operationalization of "conflict" is optimal (i.e., the costs in permissible generalization due to *strategically* imposed inclusion standards are precisely warranted) when the probability that the least intense event included will be reported by the least sensitive reporting mechanisms exactly equals the validity criterion level. However, more restric-

tween size and "intensity" (which refers only to duration and elsewhere only to violence), Morgan and Clark (1973:614) and Spilerman (n.d.) provide some independent support for our operational treatment. They report results of factor analyses which indicate that number of participants, duration and measures of damage to persons and property in racial disorders cluster along a single ("severity") dimension. We also note that, while evidence is inconclusive, we suspect a rank-ordering of size, violence and duration in importance as determinants of reporting probabilities. Some support for this ordering is presented in our study of industrial violence in Italy (Snyder and Kelly, 1976). We find that rates of violence (as reported with accounts of each strike in an official source) are five times as great as those indicated by Shorter and Tilly (1971) in a comparable study of France (in which evidence of violence is based on two Paris newspapers). Since we are largely able to dismiss institutional sources of this difference, we attribute it to considerable newspaper underreporting of small work stoppages in France, even when these strikes were violent.

tive event inclusion limitations are, of course, warranted if they are imposed on the *theoretical* grounds of hypothesized variation in causal processes across forms of conflict behavior.

We now apply the general hypotheses developed here to analyses of racial conflict in U.S. cities. Figure 1 presents a heuristic diagram of our interactive model for three types of racial conflict and two levels of media sensitivity (AP/UPI versus other cities). For event types E_1 , E_2 , and E_3 , respectively we select collective racial violence (since Danzger explicitly focuses criticism on studies of these disorders), civil rights demonstrations (to which Danzger admittedly gives primary emphasis), and

the hostile merchant-customer interactions discussed earlier. Hypothesized mean intensities (\bar{I}_n) of these event types vary, as do their frequencies. We also allow some intersection of the intensity ranges of these event types—e.g., the most intense civil rights demonstrations will manifest greater intensity than the least intense racial disorders.

As previously suggested, we hypothesize that events which meet Spilerman's (and others') racial disorder inclusion criteria are intense enough to achieve reporting validity *even in the absence* of a more sensitive (AP/UPI) news network. This expectation is shown in Figure 1, which indicates complete reporting of racial disorders [$p(E_1) = 1.00$] for *both* levels (AP/UPI

Figure 1. Heuristic Diagram of Conflict Intensity-Media Sensitivity Model of Validity, Applied to Three Types of Racial Conflict and Two Levels of Media Sensitivity

and other cities) of media sensitivity. However, the less intense event types (E_2 , E_3) should be reported with greater validity in wire service than other locations because their intensity distributions are intersected at different points by the differentially sensitive reporting networks. Therefore, we expect that analyses of racial *conflict* across U.S. cities (Danzger, 1975), but *not* studies of racial *violence* (Spilerman, 1970; Lieberman and Silverman, 1965; Downes, 1968; 1970; Jiobu, 1971; 1974; McElroy and Singell, 1973; Wanderer, 1969), will be biased. More generally, extension of the model shown in Figure 1 to N types of conflict behavior and M levels of media sensitivity is straightforward.

However, since we have not yet considered factors which affect media sensitivity (beyond the differential "efficiency" of communications networks across U.S. cities), we now pay brief attention to these issues. We anticipate that two broad classes of factors—"political climate" and contextual characteristics of conflict events themselves—determine media sensitivity to conflict behaviors. Important contextual characteristics (i.e., those which are not components of intensity) include frequency nature of participants involved and locational "visibility" *vis-à-vis* media sources. We expect a net negative relationship between frequency of an event type and its probability of being reported (although such a relationship may largely reflect the negative association between frequency and intensity). Small town newspapers are likely to report fistfights in local bars; those in major cities are not. Similarly, as industrial strike activity has evidenced secular increases in frequency and routinization in form (Shorter and Tilly, 1974), it has become a less newsworthy conflict behavior.¹³ Concerning racial disorders, this argument implies that, if any underreporting does

occur, it is more likely in cities with past disorder experience—i.e., opposite Danzger's (1975) indication that many previous conflicts sensitize the media to report such behaviors.¹⁴

Effects of other conflict characteristics on media sensitivity are more obvious, and we merely outline them here. Media sources are more likely to report events in which coercive forces are involved (since official statements on such incidents are usually forthcoming) and those in which participants are already public figures. Data validity also may be affected by the interaction of types of participants and political leanings of the reporting media¹⁵ and, as we have indicated, locational proximity to the relevant communications networks (including AP/UPI) is salient.

Finally, aspects of the "political climate" in which conflict occurs regularly affect the sensitivity of news sources of data. These effects often are manifested directly, as in governmental suppression of the press. However, they also may occur indirectly, for example when a single dramatic event raises public interest in an entire class of similar events. This last point suggests that, under some conditions, the rank-ordered reporting probabilities of conflict events which are based on their relative intensities will be rearranged. With few exceptions, however, we doubt that events of relatively low intensity remain newsworthy for long and, consequently, that these discontinuities in the linear intensity-reporting probability relationship are systematic.¹⁶

In summary, we have presented a model

¹⁴ We agree, however, that in the very short run rapid upsurges of previously infrequent forms of conflict may result in greater media sensitivity to such events. In the longer run, we expect our above arguments concerning frequency to take precedence, which implies a curvilinear (inverted U) relationship over time between frequency and these irregular event types.

¹⁵ For example, during the Weimar Republic in Germany, it appears that socialist newspapers were more likely to report attacks of left-wing groups, while rightist papers more regularly listed attacks on Nazis (personal communication, Professor James Diehl, Department of History, Indiana University).

¹⁶ This hypothesis is based on the assumption that intensity reflects the "importance" of conflict behavior in relatively invariant fashion.

¹³ We do not imply that these secular changes in frequency and routinization have undermined the completeness of strike reporting in official statistical compendia. However, in extreme cases, such as the French sitdown strike waves of 1936, unprecedented magnitudes of conflict can break down the reporting mechanism itself (Shorter and Tilly, 1974). Of course, this outcome is highly improbable with newspaper sources.

in which validity in conflict data derived from newspapers and other standard sources depends on the interaction between the intensity of conflict events and the sensitivity of reporting mechanisms. Although this model cannot *a priori* indicate levels of indicator validity with precision, it does provide clear guidelines for discriminating between those analyses of conflict behaviors which are likely based on valid versus contaminated data. Consequently, our interactive treatment differs considerably from Danzger's (1975) arguments, which (a) attribute bias solely to differential media sensitivity and (b) therefore conclude that empirical studies of conflict which utilize news reports are *all* invalid. In the following section, we report results of two sets of analyses which test these alternative arguments.

Analysis 1: Racial Disorders (1965-1969)

Data and method. For this analysis, information on the incidence of racial disorder was coded for 1965 through 1969 from reports issued by the Lemberg Center, the Senate Committee on Government Operations and the Congressional Quarterly.¹⁷ We have maintained separate files by year for the disorder data in order to examine (a) possible parameter shifts over time as a function of the changing form of racial disorders during this period¹⁸ and

¹⁷ Particular Lemberg Center Reports include: *Riot Data Review*, for May, 1968; August, 1968; February, 1969; *U.S. Race-Related Civil Disorders*, for January-June, 1969; July-December, 1969; and *Compilation of 1967 Disorders*. Our second source is the *Staff Study of Major Riots and Civil Disorders—1965 through July 31, 1968*, of the Permanent Subcommittee on Investigations of the Committee on Government Operations, 1968. We also used the Congressional Quarterly's *Civil Disorder Chronology*, September, 1967. All of these publications rely almost entirely on newspaper reports and thus conform to the sources employed by Danzger (1975) and Spilerman (1970; 1971). In some cases, our sources also communicated with city officials and local newspapers, generally to supplement other reports.

¹⁸ See Baskin et al. (1971) for a discussion of changes over time in the form and character of riots. For example, the typical precipitant changed from "random" encounters of black citizens with police in 1967 to consequences of the assassination of Martin Luther King in 1968.

(b) Danzger's arguments versus ours on the relationship between previous conflict and reporting bias. We exclude the years 1961 through 1964 because the very small number of disorders does not permit separate yearly analyses. Our operational definition of a disorder approximates that employed by Spilerman (1970; 1971), i.e., thirty or more blacks, doing damage to persons and/or property, and not occurring at or in school. However, spontaneity of the event was not a necessary criterion for inclusion because, in many cases, it was impossible to differentiate between spontaneous and nonspontaneous disorders with any confidence. Table 1 shows the distribution of disorder frequency in Spilerman's study and ours for the overlapping years (1965-1968). Despite somewhat different definitions, figures presented in Table 1 indicate that the two distributions are generally comparable.

Our independent variables come from two sources. Information on the location of wire service offices was obtained from interviews with officials of AP and UPI, who made available Bureau Directories. Although these directories were compiled for 1974, both Bureau officials assured us that additions since 1965 have been minimal. All other city characteristics are taken from the Alford-Aiken Governmental Units Analysis data set used by Spilerman. This file contains data on all 673 cities in the continental United States which had total populations greater than twenty-five thousand in 1960 (except for his missing data, these cities are identical to those in Danzger's study).

Our analyses of the effect of wire services on the reported frequency of racial disorders proceed (as do most of Danzger's) on the assumption that this relationship should be estimated and interpreted only *after* factors associated with both the dependent variable and the independent variable of interest (AP/UPI) are controlled.¹⁹ Failure to include these controls

¹⁹ This stepwise procedure is employed because other independent variables are *substantively* related to patterns of disorder frequency, while the wire service explanation is an *artifactual* one. Since wire service location is associated with sub-

* Adapted from Spilerman (1970:631).

greatly increases the danger of attributing substantive importance to spurious findings (Blalock, 1968). A related and equally important consideration is proper specification of the functional form of relationships between variables. If, in fact, particular independent variables exhibit nonlinear effects on the dependent variable (e.g., Spilerman, 1971:434-9), failure to specify them as such will misstate the true relationship and may again be a source of spuriousness.

Findings and discussion. Given these methodological points, we estimate the net contribution of wire service location to explained variance in disorder frequency with a model identical to that employed by Danzger (1975:582). Although we recognize that these disorders may differ from other racial conflicts, previous research on racial disturbances (Spilerman, 1970; 1971; Morgan and Clark, 1973) justifies the inclusion of the following independent variables: total nonwhite population in 1960 (N. Nonwhite); the year in which the city first attained a population of twenty-five thousand (City Age); a dummy variable scored one for those cities located in the Census South and zero for all others (South); the total number of unemployed persons in 1960 (N. Unemp); and a dummy variable equal to one for cities which have AP and/or UPI wire service offices and zero otherwise (AP/UPI). The dependent variables are the log transformed (X+1) total cumulated (Total) and yearly disorder frequencies (1965-1969).

Table 2 displays results of the regressions of these disorder measures on the independent variables described above; the latter enters the equations in the order presented in the table. Two preliminary conclusions emerge from this set of regressions. First, AP/UPI does not account for large increments in explained variance of disorder frequency. For total frequency, however, the

stantive sources of disorder (e.g., nonwhite population size, since AP and UPI offices are located in larger cities), if we entered the variables simultaneously in the equation, the variance explained in common would be apportioned among their partial regression coefficients (Gordon, 1968).

net influence of wire service reporting is small but not negligible (we estimate an R^2 change=.028 versus Danzger's .054 for racial conflict, although the two figures are not comparable).²⁰ Except for 1969, the impact of AP/UPI in the separate yearly equations is trivial (as we show later, proper specification of the nonwhite population variable eliminates even the weak evidence of wire service bias indicated here). After controlling for plausible sources of racial disorder, the effect of wire service location on reported frequency is at best of tenuous substantive importance. These results therefore tend to support our argument that event intensity is an important determinant of validity in conflict data and suggest that Danzger's conclusions concerning bias in previous studies of racial disturbances are largely mistaken.

Second, net of this general conclusion of minimal bias, the yearly equations indicate some temporal fluctuation in the relationship between wire service location and disorder frequency. Corresponding partial regression coefficients for AP/UPI (where all variables are entered simultaneously; results not shown here) range from small and *negative* for 1965 to increasingly positive

for subsequent years and the cumulative total.²¹ This pattern of increase is opposite that expected by Danzger; he argues that previous conflict sensitizes the media to report current episodes. More specifically, fully eighty percent of the cities which reported at least one racial disorder (by our definition) in 1969 had experienced a previous event during the period covered by our data. Over seventy percent of 1968 disorder cities, but less than forty-five percent in 1967 and fourteen percent in 1966 had reported earlier events. On Danzger's argument and this distribution of disorders, we should expect smaller effects of AP/UPI for the later years because larger percentages of cities were experiencing second, third, fourth, etc. events when media attention presumably was more focused on them. However, these findings are inconsistent with Danzger's expectations. Instead, our hypothesized negative relationship between frequency and reporting probabilities better explains these slight increases over time in the influence of AP/UPI.

In a second set of regression analyses, we address the specification issue raised earlier. In particular, Spilerman (1971) shows that the relationship between non-white population size and disorder frequency is clearly nonlinear, i.e., approaches a modified logistic curve. This functional form represents two substantive analogues:

²⁰ We report significance tests only for AP/UPI and only to avoid claims that we have withheld any information which might be favorable for Danzger's arguments. However, since these cities constitute a population rather than a sample, we stress that significance tests are not interpretable in conventional fashion. Moreover, given the large N, we prefer to rely on criteria of substantive significance (cf. Frideres and Taylor, 1972); we consider that increments of two to three percent marginally meet such criteria.

²¹ In this case, we use metric coefficients because explained variance measures are not comparable insofar as they depend on the total variances of the relevant variables (e.g., Cain and Watts, 1970).

Table 3. Increments in Variance Explained by AP/UIP in Regressions of Yearly and Total Racial Disorder Frequency on City Characteristics: Non-South Cities *

	Disorder Frequency

the "critical mass" (minimum nonwhite population below which disorder does not occur) and "ceiling" (diminishing rates of increase in disorder probabilities for very large nonwhite populations) effects. Spilerman (1971:436) approximates this form of relationship with the following ordinary least-squares equation: $D = a + b_1 \log N + b_2 (\log N)^2$, where D = disorder frequency and N = Negro (nonwhite) population size. Following Spilerman, we employ this equation for both South and non-South cities which had nonwhite populations greater than one thousand in 1960. Tables 3 and 4 report these nonlinear regression results for the non-South and South, respectively. This specification of nonwhite population is consistently superior to that employed in our first set of regressions (based on analyses of the comparable subset of cities), although this advantage is less pronounced in the year-specific equations. Of interest here, however, is the impact of the wire service variable. For Southern cities, the

increment in variance explained by AP/UIP is small though nontrivial in 1969 only, and negligible for other years and for total frequency. Moreover, the net effect of AP/UIP for the non-South is essentially zero in five of the six regressions; additionally, the regression coefficient of AP/UIP in the equation for 1965 is *negative*. Therefore, these results provide considerable support for our hypotheses concerning the importance of conflict intensity on reporting validity and no evidence for Danzger's argument of bias in studies of racial disorder. These findings also vitiate one of Danzger's (1975:582) major conclusions, that "a new assessment of the number required for a 'critical mass' or a 'ceiling effect' is required in light of the contamination of the data." A more appropriate conclusion is that, once these effects have been properly specified, there is no indication of such contamination. In general, we conclude, as expected, that previous analyses of racial disorders are valid.

*Analysis 2: Collective Protest
(May-October, 1968)*

Data and method. In this second analysis of wire service reporting bias, we employ data gathered by Eisinger (1973) on collective protest events occurring in 43 U.S. cities from May through October, 1968. Eisinger's data are of unique value for our purposes because information on protest events for these cities is based on *daily readings of local newspapers for each city* over this six-month period. This independent source of information therefore allows us to determine which protests were *also* reported in the *Times* according to differential characteristics of events (including their location in AP/UPI versus other cities).

Eisinger selected only cities which had 1968 populations between one hundred thousand and one million persons, in order to reduce distorting effects of size (cf. Eisinger, 1973:15, 28, for precise details on sampling framework and the list of included cities). Given this relatively large minimum size criterion, a high proportion of these cities (29 of 43 = .674) have AP and/or UPI offices. Inclusion of a protest event required some evidence of planning ("marches, sit-ins, demonstrations, pickets, protest meetings or rallies"). Since Eisinger was concerned with the relationship between urban political structure and protests against local government, inclusion criteria were further limited:

only those [events] carried out by two or more individuals and directed at local governmental agencies, officials or institutions were finally coded. The data do not include, then, campus protests or antiwar or anti-draft protests. No instances of rioting, ambushes, shootings, assaults, looting or threatened violence were recorded, even if the perpetrators or their victims attributed such behavior to political motivations. If, however, violence broke out at the site of a peaceful protest and was a direct result of it, this was recorded. (Eisinger, 1973:16)

However, only seven of the total of 120 protest events are violent.

In one analysis of these data, we examined the net effect of AP/UPI on variation across cities in protest frequency (as reported by the 43 local newspapers). This

first analysis by no means constitutes a test of our arguments versus Danzger's; both would expect an absence of reporting bias. However, a positive effect of AP/UPI under these conditions would suggest that Danzger's findings might not reflect differential reporting but, instead, some other factor uncontrolled in his analyses. Although there is a weak zero-order relationship between AP/UPI and protest frequency ($r=0.105$), it is entirely eliminated in every multivariate model estimated (which variously included measures of population size, form of city government, urban occupational structure and a dummy variable for Model Cities Grant during the 1960s). These results suggest that Danzger's findings that AP/UPI biases reports of racial conflict are not spurious.

Our second analysis of Eisinger's data, however, is the strongest test of our intensity-sensitivity model versus Danzger's argument of AP/UPI reporting bias. We originally attempted to use the *Times Index* to determine which of Eisinger's protest incidents also were reported in the *Times*. However, since information in the *Index* was too sketchy, assistants read through the *Times* itself for each day of the six-month period in order to "match" reports to Eisinger's events. After this matching procedure was completed, we could analyze reporting probability as a function of event intensity components (size, duration and violence from Eisinger's local newspaper data on each protest) and whether or not the incident occurred in an AP/UPI city. Specifically, we estimate the following equation: $NYT = a + b_1S + b_2D + b_3V + b_4W$, where NYT = a dummy variable scored one if an event was reported in the *Times* and zero otherwise; S = size (total number of participants, in hundreds); D = duration in days; V = a dummy variable for violence (1=yes; 0=no); and W = a dummy variable for wire service location (1=protest occurred in an AP/UPI city; 0=no wire service). We recognize the limitations in time, space and form of these protest events. However, these analyses are particularly important insofar as, to our knowledge, there are no previous empirical investigations of the de-

terminants of event-reporting probabilities.²²

Findings and discussion. One of our most important findings is the descriptive point that only 22 of Eisinger's 120 protests (18.3 percent) were also reported in the *Times*. Moreover, of all protests in which race of participants was identified (95 of the 120 cases), 73 percent involved either all black (52 percent) or mixed black and white (21 percent) participants, which would qualify them (had they occurred earlier) for Danzger's sample of racial conflicts. Since it is highly implausible that racial disorders were so underreported (i.e., only about one in five), this finding is consistent with our argument that differences in event intensity according to the form of conflict (protests versus violent disturbances) strongly affect reporting probabilities.²³

However, even within the limited (and relatively low) intensity range of the single form—protest behavior—we expect that intensity components will determine reporting validity. Equation (1) in Table 5 presents metric (b) and standardized (B, or beta) partial regression coefficients for the model described above.²⁴ In this case, the partial coefficients are preferable to the net increments to explained variance procedure used earlier because, since the occurrence of protest is now a given, there is no need to

control for substantive sources of frequency before entering AP/UIP. Raw coefficients (multiplied by 100) may be interpreted as the net percentage increase or decrease in event-reporting probabilities per unit increase in the independent variable. We also note that the regressions are based on 91 protests for which data on all variables are available.²⁵

The results shown in equation (1) of Table 5 are highly consistent with our arguments. Net of the three event intensity components (size, duration and violence), the effect of a protest's location in AP/UIP cities on its probability of being reported in the *Times* is very small and in the wrong direction.²⁶ Moreover, the coefficients of all three components of intensity are in the expected positive direction. In the case of size and duration, they are also of substantial magnitude (we attribute much of the weak impact of violence to its extremely small variance in these data). Consequently, these findings show the importance of event characteristics in determining their reporting probabilities (validity). The results also strongly challenge Danzger's emphasis on AP/UIP as the only important influence, as well as his (implicit) assumption that all conflict events are homogeneous with respect to reporting validity.

This is not to say, however, that the *Times* reports are entirely valid net of event intensity characteristics. We noticed that very few protests occurring in Western cities appeared in the *Times*, which suggests

²² In making this claim, we are well aware of previous studies by White (1950), Breed (1958) and Molotch and Lester (1975). However, the former two deal with selectivity of reports according to topics rather than event characteristics. The latter analyzes extent and type of coverage of aspects of a single event.

²³ Our previous analyses of racial disturbances strictly test only the hypothesis that disorders were not differentially reported across cities. However, we constructed that hypothesis on the assumption of complete reporting, on which the above statement is also based.

²⁴ The dummy dependent variable violates assumptions of disturbance homoscedasticity (Goldberger, 1964:249). Although the coefficients themselves are unbiased estimates (Ashenfelter, 1969:645), we do not report significance tests since standard errors would be biased under these conditions. However, our arguments do not depend on such tests; comparisons of the standardized regression coefficients are appropriate for this purpose.

²⁵ Eisinger (1973) reports the size of events in eleven categories. We recoded this variable as the midpoint of each of his size intervals, and assigned an arbitrary value of 2500 participants to the two cases which fell in the "2001 or more" category. We also relied on the *Times* reports for participants estimates in three cases where this variable was "undetermined" in Eisinger's data. Eisinger coded duration in five categories corresponding to one, two, three, four and five or more days, which slightly attenuates its variance and, probably, its effect on reporting bias in our analyses.

²⁶ Seymour Spilerman suggested (personal communication) an explanation for the slight, but counterintuitive, negative effect of AP/UIP in both this and the earlier analyses of disorders. Since AP/UIP offices and greater levels of conflict both are found disproportionately in larger communities, a given event should be marginally less newsworthy in wire service cities.

Table 5. Dummy Variable Regression Analyses of *New York Times* Protest Reporting Validity on Indicators of Event Intensity and Media Bias, May-October, 1968^a

^a See text for definition and measurement of variables.

a regional bias in coverage. Therefore, we created two dummy variables for regional location of cities: West (scored one for protests in cities west of the Mississippi River and zero otherwise) and South (1 = Census South; 0 = non-South). As the negative coefficients of these variables in equation (2) indicate, there is regional bias in the *Times* coverage, although underreporting is substantial only for protests occurring in Western cities.²⁷ Although inclusion of the regional dummy variables slightly reduces the effects of intensity components and AP/UPI from those presented in equation (1), our substantive conclusions concerning these indicators are not altered. These results show that validity depends upon both the intensity of events and the sensitivity of the reporting media, although in this case differential sensitivity is based on region rather than AP/UPI location. More generally, these findings provide strong support for the conflict intensity-media sensitivity model of validity in newspaper data developed in this paper.

SUMMARY AND CONCLUSIONS

We began this paper by challenging Danzger's (1975) conclusion, based on his analysis of racial conflict, that empirical studies which rely on newspaper data are biased. In particular, we doubted (1) Danzger's assumption that all forms of conflict are homogeneous and therefore equally likely (for any given type of communications network) to be reported; (2) his consequent treatment of validity as solely dependent on the reporting mechanism; (3) his claim that other analyses, especially those of disorder frequency, are invalid. Our findings in two discrete analyses—of

²⁷ Given the substantial effect on reporting of region in this analysis, we also included the West variable in our previous investigation of racial disorders, but found its influence to be negligible. This finding provides further support for our argument that racial disorders were intense enough to be reported even if they occurred in places for which media sources were relatively insensitive. We also tested for bias according to the race of participants and other characteristics of these protest events, but found these factors to be unimportant.

collective racial violence across 673 U.S. cities from 1965 to 1969 and of collective protest occurring in 43 cities during May-October, 1968—sharply contradict each of Danzger's points. Both analyses indicate that event characteristics are also important determinants of validity in news data, that conflict behaviors are differentially likely to be reported according to their intensity, and that previous studies of racial disorders are unbiased.

These results were expected from the alternative model of validity in conflict data developed in this paper. In this model, we specify validity as a function of event intensity and media sensitivity. Event intensity is dependent on size, duration and violence components. Intensity determines the relative probabilities that different forms of conflict behavior will be reported. Precise reporting probabilities, however, cannot be determined in the absence of information concerning media sensitivity to conflict events. Media sensitivity is dependent on "political climate" and on contextual characteristics of events (including their locational proximity to relevant reporting networks). Unbiased conflict data will be obtained when the probability that the least intense form of included behavior will be reported by the least sensitive media source exceeds a given validity criterion level. When forms of conflict behavior do not meet this validity criterion, they vitiate the theoretical advantage of generalization to a broader range of conflict which presumably follows from their inclusion. Our model specifies that the "multiple-indicator" strategies for measuring conflict which prevail in cross-national studies (e.g., Feierabend and Feierabend, 1966; Gurr, 1968; Hibbs, 1973; Rummel, 1963; Tanter, 1966) are particularly likely to be biased. Conversely, "form-specific" studies are generally valid, especially insofar as they limit consideration to behaviors of relatively high intensity.²⁸

²⁸ In some cases, multiple indicator studies also place limitations on event qualification criteria (e.g., Gurr, 1968, purports to restrict events to those with more than one thousand participants). Although this procedure reduces validity problems, it rarely eliminates them, given the range of included event types (e.g., Gurr includes

We recognize the major limitation of this conflict intensity-media sensitivity model of validity in news and other sources of conflict data. It cannot *a priori* specify precise levels of validity for different forms of conflict behavior. Consequently, we do not, in any sense, propose that our model is an adequate substitute for location of independent data sources and direct verification of validity (as we have done for collective protest events). However, such procedures are costly and, in many cases, impossible. Moreover, they are unlikely to be undertaken for the large number of data sets on which previous empirical analyses are based. Given these practical constraints, our model is particularly valuable insofar as it specifies clear guidelines for assessing the validity of past research and for designing future empirical analyses of conflict.

Finally, our findings are relevant to more general issues concerning bias in newspaper reports. Although we do not address work on validity in content, some analyses of media bias extend their treatment of printed news as social construction to selectivity issues. For example, White's (1950) case study of a wire editor's decisions presents strong evidence that the subject's personal feelings influence content, but erroneously concludes that they also determine his choice of topics.²⁹ Similarly, Molotch and Lester (1974:110) emphasize "... the fact that all events are socially constructed and their 'newsworthiness' is not contained in their objective features." Our analyses of conflict data challenge that view since our results clearly indicate the importance of objective features as determinants of reporting bias. Validity in newspaper data must be considered as a function of *both* media

localized rebellions, mutinies, plots and purges which are plausibly underreported for many locations). To some extent, explicit incorporation of assumptions concerning measurement error could reduce the validity problems in multiple-indicator analyses, but such techniques are consistently absent from empirical work in this area.

²⁹ The subject was instructed to save all wire copy during a seven-day period and note reasons for each item rejected. Despite White's conclusion of biased selection by topic, we compute a remarkably high correlation of .96 between the column inches of wire copy received and those actually published on thirteen topic areas (data from White, 1950:385).

bias and the objective characteristics of events themselves.

WORK VALUES AND JOB REWARDS: A THEORY OF JOB SATISFACTION*

ARNE L. KALLEBERG

Indiana University

American Sociological Review 1977, Vol. 42 (February):124-143

This paper attempts to develop a theory of job satisfaction which incorporates differences in work values and perceived job characteristics as key explanatory variables. It empirically examines the relationship between job satisfaction and the work values and job rewards associated with six dimensions of work—intrinsic, convenience, financial, relations with co-workers, career opportunities and resource adequacy. It is found that work values have independent effects on job satisfaction. The extent to which workers are able to obtain perceived job rewards is conceptualized to be a function of their degree of control over their employment situations. The paper also seeks to develop a framework which links the variation in the job satisfactions of workers to the factors that influence the degree of their control over the attainment of job rewards in American society. The analyses in this paper are based on data from the 1972-73 Quality of Employment Survey.

The concept of job satisfaction traditionally has been of great interest to social scientists concerned with the problems of work in an industrial society. Many have been interested in job satisfaction, for example, as a result of a personal value system which assumes that work which enables satisfaction of one's needs furthers the dignity of the human individual, whereas work without these characteristics limits the development of personal potential and is, therefore, to be negatively valued. Thus, it is important to examine these issues in order, hopefully, to improve the work experiences of individuals as an end in itself. Other social scientists have been interested

in this concept because of evidence that has linked the degree of satisfaction with work to the quality of one's life outside the work role—especially one's physical and mental health. Still others were motivated to study job satisfaction out of a desire to improve productivity and organizational functioning by improving the quality of work experiences of employees. While these concerns have their bases in different perspectives, they share the recognition of the importance of the job in the total life experience of the individual and the desirability of a positive work experience.

Three types of explanations historically have been suggested to account for the variation in the job satisfactions of workers. The first has sought to explain this variation solely in terms of the personalities of individual workers and has attempted to establish a relationship between measures of adjustment or neuroticism and job satisfaction (see Vroom, 1964, for a discussion of this line of reasoning). While personality variables undoubtedly have some effect on job satisfaction, such explanations are inadequate because they ignore the association of job satisfaction with characteristics of the job.

A second explanation views variation in job satisfaction solely as a function of differences in the nature of jobs people perform. In the past, this has been the numer-

* This is a revision of a paper presented at the 70th annual meetings of the American Sociological Association, San Francisco, August 25-29, 1975, and it reports portions of an unpublished Ph.D. dissertation (Department of Sociology, the University of Wisconsin, Madison, 1975). I am grateful to Michael Aiken, Paul Allison, Arthur Goldberger, Warren Hagstrom, Robert Hauser, Melvin Kohn, Jack Ladinsky and Aage Sørensen for comments on that work and to three anonymous referees and Lowell Hargens for useful criticisms of earlier versions of this paper. I am, of course, responsible for any errors. The research was supported by Grant GMO-1526 from the National Institutes of General Medical Sciences. I also wish to thank the Institute for Social Research at the University of Michigan for making the 1972-73 Quality of Employment Survey available for public use so promptly.

ically dominant view and studies employing this type of reasoning generally deal with two sets of variables—one a measure of a work role characteristic(s), the other a measure of job satisfaction—and attempt to establish a causal relation from the former to the latter. There is wide variation in the types of work role characteristics that have been used. Some common ones include characteristics of the organizational structure such as span of control and size (see the summary by Porter and Lawler, 1965), job content factors such as degree of specialization (e.g., Shepard, 1970), economic factors (e.g., see Massie, 1964), social factors, promotional opportunities and hours of work. (Excellent reviews of these types of studies are provided by Vroom [1964] and Herzberg et al. [1957].) Generally, these investigations have found that job satisfaction varies, often considerably, with one or more of these variables. A widely tested theory of the determinants of job satisfaction that utilizes this type of explanation is Herzberg's "two-factor" theory (Herzberg et al., 1959). This type of explanation of the variation in job satisfaction may be characterized as a "structural" one, in that the attitudes of workers are seen as a direct, one-to-one reflection of the structure of the work place. This line of reasoning has had great practical utility since it has suggested to employers ways in which they could increase the satisfactions of workers by manipulating job characteristics that are frequently under their control.

Despite the practical utility of this second type of reasoning, this view raises important theoretical problems that question its usefulness for a thorough understanding of job satisfaction. In particular, it does not consider individual differences in the satisfactions experienced by people with the same job characteristics. Such differences arise not only because people evaluate similar "objective" job characteristics differently, but also from differences in what people seek to obtain from their work.

The view that the satisfaction an individual obtains from a job is a function not only of the objective properties of that job but also of the motives of the individual

was first suggested by Morse (1953). Since that time, the major line of development of this view in sociology has occurred through the writings of British industrial sociologists adhering to the "social action" approach.¹ Leading exponents of this view are Goldthorpe and his associates (1968), who reacted against the attempts of organizational social scientists to study issues of worker satisfaction by adhering to a closed-system model wherein organizations are seen as the relevant context for explaining these issues. They argued that the question of satisfaction from work cannot be thoroughly considered without a knowledge of the meanings that individuals impute to their work activity. Studies within this perspective (e.g., Goldthorpe et al., 1968; Beynon and Blackburn, 1972; Russell, 1975) have contributed to our knowledge of job satisfaction by attempting to establish empirically the ways in which the wants and expectations that people attach to their work activity shape the attitudinal and behavioral patterns of their working lives as a whole.

A social action frame of reference which directs attention to the variety of meanings that individuals impute to their work has great potential for advancing our knowledge of job satisfaction and the quality of work experience of individuals in general. At present, however, this potential may be regarded as only a promise. There has been no successful attempt to systematically and empirically establish the way in which meanings and the various satisfactions that work provides combine to determine job

¹ The classical origins of the social action approach may be traced to Max Weber. He rejected the assumption of any objective meaning attached to actions and wished to restrict the understanding and interpretation of meaning to the subjective intentions of the actor (Gerth and Mills, 1946:58). This approach starts from the principle that if people define situations as real, they are real in their consequences and thus it takes the actors' own definitions of the situations in which they are engaged as an initial basis for the explanation of their social behavior and relationships. Such an approach may be contrasted with those which start with some general and normative psychology (or philosophy) of individual needs.

satisfaction based on a heterogeneous and diverse sample of workers. Also, no adequate conceptualization exists which systematically links these considerations to the factors that affect the attainment of jobs. The present paper attempts to partially fill these gaps in our understanding of job satisfaction.

The objectives of this paper are to conceptualize and empirically examine: (1) the way work values and job rewards combine to influence job satisfaction and (2) the factors that determine the extent to which individuals are able to obtain job rewards. This paper thus seeks to develop a model which links the variation in the job satisfactions of individuals to the factors that influence their degree of control over the attainment of these rewards in American society.²

Data

The data that will form the empirical bases for the arguments to be developed in this paper come from the 1972-73 Quality of Employment Survey. This survey was conducted by the Institute for Social Research of the University of Michigan and is representative of the national employed civilian labor force meeting certain sample eligibility criteria (see Quinn and Shepard, 1974, for a description of the survey and sampling procedures). These data were obtained through personal interviews with 1,496 persons living in housing units within the continental United States and the District of Columbia and consist of the *perceptions* of these individuals regarding characteristics of themselves, of their jobs, etc. The sample appears to be representative in its design and selection procedures and

also in its representation of various subgroups (by sex, race, occupation, etc.) in the population (cf. Kalleberg, 1975:Appendix A).

These data permit the type of comparative analysis necessary for the elaboration of a theoretical model. In contrast to previous studies within the social action perspective (e.g., Goldthorpe et al., 1968; Beynon and Blackburn, 1972), which focus on a particular organizational setting, such data allow the consideration of a wide variety of occupational and organizational factors and thus permit the investigation of a large number of such conditions on workers' values, rewards and satisfactions.

Job Satisfaction

In order to empirically examine the process underlying the notion of job satisfaction, it is necessary first to state explicitly what is implied by this concept. Job satisfaction refers to an overall affective orientation on the part of individuals toward work roles which they are presently occupying. It must be distinguished from satisfaction with specific dimensions of those work roles. This conceptualization implies that job satisfaction is a unitary concept and that individuals may be characterized by some sort of vaguely defined attitude toward their total job situation. To say that job satisfaction is a unitary concept, however, does not imply that the causes of this overall attitude are not multidimensional. Obviously, a person may be satisfied with one dimension of the job and dissatisfied with another. The assumption underlying the present view is that it is possible for individuals to balance these specific satisfactions against the specific dissatisfactions and thus to arrive at a composite satisfaction with the job as a whole (cf. Hoppock, 1935). In line with these considerations, a measure of overall job satisfaction was developed based on the responses of workers to five questions concerning how satisfied they are with their jobs as a whole. These questions included such direct inquiries as "how satisfied are you with your job" as well as such indirect measures as whether the worker would recommend the job to a friend, whether the worker plans to look

² It is, therefore, an attempt to develop a "theory" of job satisfaction, i.e., a set of generalizations that explains the variation in this phenomenon on the basis of the conditions and processes that produce this variation (cf. Blau, 1965). There are two parts to the theory: a "psychological" part, which explains the variation in job satisfaction produced by the interplay between work values and job rewards and a "sociological" part, which relates the variation in job satisfaction to factors that affect one's degree of control over the attainment of job rewards.

for a new job within the next year, whether the worker would take the same job again if given a choice, and how the job measures up to the sort of job the worker wanted when he took it. The resultant scale of job satisfaction was computed as the mean of a sum of the responses to these questions and had a reliability (Cronbach's α) of .77.³ (A detailed discussion of this measure, as well as of all the measures described in this paper, may be found in Kalleberg, 1975.) The use of a multiple-item indicator of this construct overcomes many of the problems associated with single-item measures of job satisfaction (see Kalleberg, 1974).

A worker's level of job satisfaction is a function of the range of specific satisfactions and dissatisfactions that he/she experiences with respect to the various dimensions of work. It is thus "the pleasurable emotional state resulting from the appraisal of one's job as achieving or facilitating the achievement of one's job values" (Locke, 1969). This view of the process underlying the variation in job satisfaction implies that two types of factors are operative: perceived job characteristics, which represent the amount of satisfaction available from particular dimensions of work, and work values, which represent the meanings that individuals attach to these perceived job characteristics. In order to examine this process empirically, it is necessary to develop measures of these factors.

³ Evidence for the unidimensionality of the job satisfaction scale is provided by: (1) a principal components factor analysis of the correlation matrix for the five items comprising the scale, which produced a single-factor solution accounting for 52.6% of the total variation among the items and (2) a principal factor analysis of the correlation matrix for the five general job satisfaction items and the 34 job reward items (to be discussed later). A quartimax orthogonal rotation of the factor matrix produced by this analysis revealed that the five general job satisfaction items factored out separately from the job reward items, suggesting that general job satisfaction is a unitary phenomenon and is distinct from the satisfactions associated with specific dimensions of work. These results provide no support for any "two-factor" notions of job satisfaction (cf. Herzberg et al., 1959). These factor analyses are presented in Kalleberg, 1975.

Work Values

Work may have a variety of meanings for individuals in an industrial society. Work has no inherent meaning but, rather, individuals impute such meanings to their work activity. One way to understand the variety of these meanings is to specify the range of gratifications that are available from work in an industrial society and to assess the degree to which particular individuals value each of these dimensions.⁴ Information regarding the importance of each of 34 job characteristics to the worker was obtained from respondents in the Quality of Employment Survey.⁵ The intercorrelations among these items were factor-analyzed by means of a principal factor procedure, and the factor matrix produced by this analysis was rotated by means of a quartimax orthogonal rotation. Six dimensions of work that are differentially valued emerged from this analysis.⁶ These are:

⁴ In contrast, Goldthorpe et al. (1968) classify workers on the basis of several ideal-type "orientations to work," sets of consciously experienced expectations or goals which represent the priorities one holds with respect to the work activity. Such categorizations do not appear very useful for a comparative analysis since identifying workers as motivated by a single type of reward tends to neglect their valuation and experience with respect to other dimensions. The present view is more general than that suggested by Goldthorpe et al. in that it does not assume the existence of a dominant orientation but treats this as an empirical question. If such an orientation should, in fact, empirically characterize a group of individuals, this would be reflected by their valuing highly certain dimensions of work and not valuing others.

⁵ The worker was asked: "People differ a lot in terms of which of these things are more important to them. We'd like to know how important each of these is to you." The respondent then sorted 34 cards containing names of job characteristics (e.g., the work is interesting, the hours are good, the pay is good, promotions are handled fairly) into four piles, each pile corresponding to a response category (very important, somewhat important, a little important, not at all important). See Quinn and Shepard, 1974, for a discussion.

⁶ The analysis produced 16 factors, accounting for 44.7% of the total variation among the items; only the first six factors, accounting for 85.9% of the total factor variance and 38.4% of the total variance, were interpreted. The factors explained from 6.3 to 44.7 percent of the total

An *intrinsic* dimension, which refers to those characteristics associated with the task itself—whether it is interesting, allows the worker to develop and use his/her abilities, allows the worker to be self-directive and whether the worker can see the results of the work. Valuation of this dimension thus reflects the worker's desire to be stimulated and challenged by the job and to be able to exercise acquired skills at work.

A *convenience* dimension, which refers to job characteristics that provide solid creature comforts, i.e., a "soft" job. These include: convenient travel to and from work, good hours, freedom from conflicting demands, pleasant physical surroundings, no excessive amounts of work, enough time to do the work and an opportunity to forget about personal problems. This dimension may be viewed in opposition conceptually to the intrinsic dimension as it represents a valuation of facets external to the task itself.

While the convenience dimension refers to those aspects of work that are "extrinsic" to the task itself, it does not exhaust the range of extrinsic characteristics that are differentially valued. A second extrinsic dimension refers to the *financial* dimension and includes such items as the pay, fringe benefits and job security. Valuation of this dimension reflects a worker's desire to obtain present and future monetary rewards from a job.

A third extrinsic dimension refers to *relationships with co-workers* and includes such items as whether the job permits chances to make friends, whether co-workers are friendly and helpful and whether one's co-workers take a personal interest in him/her. Valuation of this dimension reflects a worker's desire for the satisfaction of social needs from the work activity.

factor variance and from 2.8 to 20 percent of the total variance. Further, the factor analysis suggested dimensions that replicate those defined by Quinn and Shepard (1974) by means of a cluster analysis of the same items. They labeled their dimensions: challenge, comfort, financial, relations with co-workers, promotion and resource adequacy. The items included in each of the six scales in the present study are the same as those included in the corresponding scales utilized by Quinn and Shepard.

A fourth extrinsic dimension is the opportunities the job provides for a *career*, a dimension that includes such items as whether the chances for promotion are good, whether promotions are handled fairly and whether the employer is concerned about giving everyone a chance to get ahead. Valuation of this dimension represents a worker's desire for advancement and recognition.

The final dimension of work that is differentially valued may be labeled *resource adequacy*. This dimension represents workers' wishes for adequate resources with which to do their jobs well and includes such items as whether the help, equipment, authority and information required for job performance are adequate, whether co-workers are competent and helpful, and whether the supervision is conducive to task completion. This dimension of work may be viewed as being different from the previous ones in that it doesn't refer to what workers "ultimately" want from their jobs. Yet in order to obtain such rewards as money, intrinsic gratifications, advancement, etc., workers must perform adequately in their jobs. Successful role performance is not only contingent upon the demands of a role and the characteristics of the person occupying it, it also may be dependent upon the amount of resources or facilities that are supplied to the role occupant. Thus, a worker may be concerned with and value not only the ultimate rewards provided by the job, but may be equally concerned with the more immediate problem of securing resources sufficient for adequate performance in the work role (cf. Quinn, 1972).

After identifying the basic dimensions underlying the intercorrelations among the 34 importance ratings, scales measuring each of these six dimensions were developed. Scales were constructed by taking the mean of the unweighted scores on component items, thus each scale has a range from 1.0 (low valuation) to 4.0 (high valuation), despite the fact that scales have different numbers of items. Missing data on a particular item were assigned the mean of the cases present on that item. The reliability estimates for these scales, the num-

ber of items included in each scale and the intercorrelations among the scales are presented in Table 1.⁷

The concept of "work value" may be regarded as a special usage of the general concept of "value" and may be defined as the conceptions of what is desirable that individuals hold with respect to their work activity.⁸ Work values reflect the individual's awareness of the condition he seeks from the work situation, and they regulate his actions in pursuit of that condition. They thus refer to general attitudes regarding the meaning that an individual attaches to the work role as distinguished from his satisfaction with that role. The term should be distinguished further (but in common usage often is not) from related concepts that have been used previously in the literature for similar purposes. For example, values should be distinguished from expectations, which denote one's beliefs about what will occur in the future; but what is expected may not correspond to what is wanted and, conversely, what is valued may or may not correspond to what is expected. In addition, values should be distinguished from needs, which refer to the objective requirements of an organism's well-being. A value presupposes an awareness, at some level, of the object or condition sought while a need does not. The two concepts are closely related since individuals may value those factors associated with a job which satisfy their needs; but values also may be irrational and whether or not one's values correspond to his needs, it is his values which regulate his actions and determine his emotional responses. (For a

⁷ The intercorrelations among these six work-value scales were factor-analyzed (principal components factor analysis) in an attempt to discover any "higher-order" dimensions of work values that may account more parsimoniously for the covariation among them. A single factor solution was obtained, accounting for 49.2% of the total variation, suggesting that these dimensions are most usefully considered as constituting separate dimensions of work that are differentially valued.

⁸ The general definition of values from which this definition is adapted is discussed in Williams (1968). The present usage of the term "work values" corresponds to what Kohn (1969) has previously called "judgments about work" or "work orientations."

discussion of these and related issues, see Locke, 1969.)

Job Rewards

These dimensions of work that are differentially valued constitute potential sources of rewards to the worker. While valuation of particular job characteristics may, in certain cases, correspond to the availability of those characteristics, such correspondence is by no means certain in an industrial society. Given that the characteristics associated with jobs are determined relatively independently of individuals, the distribution of work values at a given point in time may not be assumed to match the distribution of opportunities for the satisfaction of these values. In order to understand the variation in workers' job satisfactions, it is necessary to consider not only the values that individuals have toward work but the types of rewards that are available as well.

Though a number of methods may be used to measure the types and amounts of rewards people receive from jobs, the relevant procedure in the present context is to ask the *worker* about the job. As Hackman and Lawler (1971) have argued, it is not the "objective" state of these characteristics that affects employee attitudes and behavior, but how they are experienced by the worker. Accordingly, information regarding "how true" each of the same 34 characteristics was for the respondent's job, which was also obtained in the Quality of Employment Survey,⁹ will be used to represent the perceived levels of the various job characteristics. The intercorrelations among these items were analyzed by means of a principal factor procedure, and the factor matrix produced by this analysis was ro-

tated by means of a quartimax orthogonal rotation.¹⁰ The six dimensions discussed previously also were found to underlie the correlations among the reward items.¹¹ Scales measuring the rewards¹² associated with each of these six dimensions were developed by taking the mean of the unweighted scores on component items; thus each scale has a range from 1.0 (low reward) to 4.0 (high reward), despite the fact that scales have different numbers of items. Missing data on a particular item were assigned the mean of the cases present on that item. The reliability estimates for these scales, the number of items included in each scale, the intercorrelations among the reward scales and the intercorrelations among the value and reward scales are presented in Table 1. It should be noted

¹⁰ The analysis produced 15 factors, accounting for 47.7% of the total variation among the items; only the first six factors, accounting for 88.4% of the total factor variance and 42.2% of the total variance, were interpreted. The factors explained from 5.4 to 42 percent of the total factor variance and from 2.6 to 20 percent of the total variance. The results with respect to the reward items also replicated the results obtained by Quinn and Shepard (see footnote 6).

¹¹ The intercorrelations among these six job reward scales were analyzed by means of a principal components factor analysis in an attempt to discover any "higher-order" dimensions of job rewards that may account more parsimoniously for the covariation among them. A single factor solution was obtained, accounting for 52.7% of the total variation, suggesting that these dimensions are most usefully considered as constituting separate dimensions of work that constitute sources of satisfaction.

¹² It may be argued that some "rewards" (i.e., convenience and resource adequacy) are most usefully considered as representing "costs" (with signs reversed). That is, high convenience and adequate resources represent, in a very real sense, decreased costs rather than increased rewards. This conceptual distinction does *not* imply the acceptance of a "two-factor" theory of satisfaction. Herzberg et al. (1959), for example, argue that rewards (job content) lead to job satisfaction while costs (job context) lead to job dissatisfaction. Similarly, Bradburn (1969) argues that avowed happiness is a function of one's positive rewards less his costs. These frameworks are based on the assumption that rewards and costs are independent of each other and functions of different sets of variables. In the present study, no evidence was found to suggest that the six "reward" variables represent two distinct dimensions (see footnote 11).

⁹ Near the end of the interview, the respondent was asked: "Here are some cards that describe different aspects of a person's job. I'd like you to put each white card below the pink card which best reflects *how true* you feel each is of *your* job." The respondent then sorted 34 cards containing the names of the same 34 job characteristics into four piles, each pile corresponding to a response category (very true, somewhat true, a little true, not at all true). See Quinn and Shepard, 1974.

further that the same job characteristics used in a particular valuation scale were used in the corresponding reward scale.

It should be clearly understood what these "job reward" measures do and do not represent. They are evaluative judgments on the part of respondents concerning features of their jobs (e.g., the pay is good, the work is interesting); in this sense, they may be regarded as representing measures of satisfaction with the various dimensions of jobs. They *do not* represent "objective" properties of jobs. The correspondence between actual and perceived properties of jobs constitutes a much-needed area of research, since it would shed light on the crucial policy-related question of how much of the variation in job satisfaction is produced by "objective" as opposed to "subjective" factors. While the present data preclude a serious examination of this issue, there is evidence to suggest that such ratings of job characteristics made by individuals do not appear unrealistic in light of our knowledge of occupational realities (see the discussion of this issue in Kalleberg, 1975:ch. 4).

One might argue that the value and reward dimensions are not independent, mainly because of instrument effect and weakness of measurement. Despite their spatial separation in the interview schedule, information regarding values and rewards was obtained from the same interview and these scales contain the same

items with different questions. One might also argue that values and rewards do not represent independent dimensions because people typically do not make a distinction between them. In order to assess the validity of these arguments, the intercorrelations among the six work-value and the six job-reward scales were factor-analyzed. The results of this analysis are presented in Table 2. Factor I consists of similarities among the job-reward measures, while Factor II involves the relationships among the work-value scales. While the analysis suggested that there may be a "methods bias" in the relationship between the intrinsic value and reward scales (Factor III) and between the co-workers scales (Factor IV), the loadings of these scales on these factors are relatively small, as is the amount of variation explained by these factors. The general conclusions suggested by Table 2 are that the reward and value scales represent independent constructs and that the amount of instrument effect is small.

Effects of Values and Rewards on Job Satisfaction

It has been argued that job satisfaction is a function of both work values and job rewards. Such a statement does not, by itself, constitute a great advance toward an understanding of the nature of the process underlying the concept of job satisfaction. A theoretical understanding of the nature

^a Zero-order correlations of values and rewards with job satisfaction.

^b Regressions of job satisfaction on values and rewards associated with a particular dimension separately (standardized coefficients). All coefficients are statistically significant at a p-value less than .001.

^c Unstandardized coefficients from the regression of job satisfaction on all values and rewards simultaneously (equation (1) in the text). $R^2 = .364$; constant = 1.680.

^d Unstandardized coefficients obtained from estimating equation (2) in the text. For each dimension, the "reward" coefficient corresponds to the R_i term in equation (2), while the "value" coefficient in the table corresponds to the coefficient for the $V_i R_i$ term. $R^2 = .353$; constant = .330.

^e Standardized coefficients from the regression of job satisfaction on the six "specific satisfaction" variables.

* $p \leq .05$.

** $p \leq .01$.

of this process requires a precise specification of the manner in which particular values and rewards combine to influence overall job satisfaction.

Clues regarding the interplay among values, rewards and job satisfaction are provided initially by an examination of their zero-order correlations. The correlations between job satisfaction and each value and reward are presented in the first column of Table 3. Rewards are positively and relatively highly correlated with job satisfaction, a result probably explained by the fact that the greater the perceived rewards one obtains from these specific dimensions of the job, the greater the satisfaction with the job in general. Values, on the other hand, are correlated near zero with job satisfaction. This might suggest that rewards may be "suppressing" the association between values and job satisfaction, which means it

is necessary to control for one of these variables when examining the effects of the other.

The second column of Table 3 presents the standardized coefficients obtained from regressing job satisfaction on both the values and rewards associated with a particular dimension of work. The pattern of these results supports the interpretation of a suppressor effect—namely, that by removing the positive association of values and job satisfaction produced by the positive correlation of values and rewards, the negative net effect of values on job satisfaction is revealed. When each dimension is considered separately, rewards have a large and positive effect on job satisfaction while values have a smaller but statistically significant (beyond $p = .001$) negative effect on job satisfaction.

In order to examine the net effects of

these values and rewards on job satisfaction, the latter was regressed on all values and rewards simultaneously. The results of this regression are presented in the third column of Table 3. These findings suggest that rewards generally have greater effects on job satisfaction than do values; rewards, furthermore, have positive net effects on job satisfaction while values generally have negative net effects. While some values do not have significant net effects on job satisfaction, a consideration of these factors constitutes an empirical as well as a theoretical improvement over a model which includes only rewards.¹³

The model underlying the coefficients in columns 2 and 3 is an *additive* one. The effect of an increase in the level of a perceived job characteristic is always positive and does not depend on the strength of one's desire for that reward, while the effect of an increase in valuation on job satisfaction is always negative and does not depend on the availability of the characteristic. Furthermore, it assumes that these effects are *linear*. This model (from Table 3, column 3) can be represented as:

$$JS = a + \sum_{i=1}^6 b_i R_i + \sum_{i=1}^6 c_i V_i + e \quad (1)$$

where JS is job satisfaction, R stands for a type of reward, V stands for the value or importance of that type of reward and *i* varies over the six types of rewards and values. In this model, the effects of rewards on job satisfaction (the b_i) are the same regardless of how important workers consider these rewards to be. However, for any given level of a reward, there will be variation in job satisfaction produced by the

variation in the valuation of that reward; these differences are represented by the c_i . The c_i are negative because for a given level of rewards (i.e., holding rewards constant), the more one values those rewards the more likely it is that these values are not fulfilled.¹⁴ The model implies that, in the aggregate, the highest levels of job satisfaction will be experienced by those workers with high rewards and low values, while the lowest levels of job satisfaction will be experienced by those workers with low rewards and high values.

While additive models constitute a major way that the relationship of job satisfaction to its components has been operationalized (Vroom, 1964), researchers holding this view typically have described this process by means of a difference score (e.g., Kuhlén, 1963). These models differ from equation (1) in that the effects of rewards and values on job satisfaction are assumed to be equal (though opposite in sign). This assumption amounts to a constraint on the coefficients of R and V which forces them to be equal, a constraint which has little theoretical or empirical justification. As the results in columns 2 and 3 of Table 3 show, rewards tend to have greater effects on job satisfaction than do values. Thus, it is not the correspondence of values to rewards that produces job satisfaction (if by "correspondence" we mean similarities in absolute levels of the variables); rather, both values and rewards have independent (but unequal) effects on job satisfaction.

One might argue that equation (1) is not an appropriate representation of the manner in which values and perceived job characteristics combine to influence overall job satisfaction. In particular, one might dispute the assumption that values have independent effects on job satisfaction and argue that a model in which values interact with rewards is more appropriate.¹⁵ Inter-

¹³ The R^2 for the present model is .364; the R^2 for a model containing only rewards as independent variables is .328. For some dimensions (i.e., financial and resource adequacy), rewards have a significant effect on job satisfaction while values do not. That is, workers who perceive they obtain greater financial rewards will tend to be more satisfied regardless of their values, and the absence of characteristics implied by resource adequacy such as role ambiguity, poor supervision and incompetent co-workers are oppressive job conditions for nearly everyone, regardless of their values.

¹⁴ Morse (1953:28) also suggested an additive view of the interplay among values, rewards and job satisfaction when she argued: "the greater the amount the individual gets, the greater his satisfaction and, at the same time, the more the individual still desires, the less his satisfaction."

¹⁵ One might also accept the additive form of the model, but argue that the assumption of

action models constitute the second major way that the relationship of job satisfaction to its components has been operationalized (e.g., Vroom, 1964; Schaffer, 1954; Hackman and Lawler, 1971; Wanous, 1974), although there has been no attempt in these studies to compare the explanatory power of the interaction models to that of additive models. While there are a large number of ways in which interactions between values and rewards in determining job satisfaction may be specified, a theoretically attractive version is represented by:

$$JS = a + \sum_{i=1}^6 b_i R_i + \sum_{i=1}^6 c_i V_i R_i + e. \quad (2)$$

Here the b_i represent the effects of the six perceived job characteristics on job satisfaction when the worker considers them relatively unimportant, and the c_i represent the additional effects of the same rewards as the value of the rewards to the worker increases. In contrast to equation (1), this model implies that the effects of job rewards on job satisfaction depend on the levels of valuation of the rewards.

The fourth column of Table 3 reports the coefficients obtained from estimating equation (2). Three factors suggest that equation (2) is less appropriate than equation (1) for representing the relationships among values, rewards and job satisfaction. First, equation (1) explains more of the variance in job satisfaction than equation

(2) (.364 versus .353). Second, the c_i in equation (2) are *negative*, whereas the reasoning underlying this model would have assumed the c_i to be positive. That is, an interaction model such as equation (2) assumes that highly valued rewards have greater effects on job satisfaction than rewards that are unimportant; equation (2) yields empirical results that contradict this assumption. Finally, equation (2) is also problematic in that the collinearity between the R_i and $V_i R_i$ terms for each dimension is very high (from .77 to .90); this makes it difficult to distinguish the respective effects of these terms. Therefore, equation (1) will be considered to be a more appropriate representation of the manner in which values and rewards combine to influence overall job satisfaction, at least in these data.¹⁶

The above analysis has suggested that work values have independent effects on job satisfaction. One might conclude from this that characteristics of jobs do not interact with work values to produce satisfaction; this would be incorrect. It is important to remember that the "job-reward" measures discussed in this paper are *perceptions* of job characteristics. The relationship between actual and perceived job characteristics constitutes a source of individual differences in satisfaction with specific dimensions of jobs that are not considered in this paper. The possibility remains very plausible that values (or related concepts, such as needs) interact with the "objective" job characteristics to produce evaluative judgments about those characteristics. For example, individuals are likely to develop judgments about or even to merely *notice* characteristics of their jobs to the extent to which the individuals value these char-

linearity implied by equation (1) is inappropriate. Equation (1) implies that having more than an adequate opportunity for the achievement of a particular value (i.e., cases where $J > V$) increases job satisfaction. One might argue that such opportunities would be frustrating to the individual low on the particular value if, along with the opportunity, colleagues or superiors expect or demand a high level of motivation of the particular type. The veracity of the linearity assumption within the context of an additive model was examined by comparing the R^2 values for models of the form of equation (1) with the R^2 values for two alternative specifications of an additive model which did not imply linearity (1) $JS = a + b|R - V| + e$ and (2) a model where the V and R for each dimension were divided into three categories each. Equation (1) yielded higher R^2 values in both cases. For an elaboration, see Kalleberg, 1975.

¹⁶ Additive models of the form of equation (1) are compared with a number of alternate specifications of models incorporating interactions between values and rewards in Kalleberg (1975). One such model combined the features of equations (1) and (2); i.e., $V_i R_i$ terms were added to equation (1). As was the case with equation (2), the very high collinearity between the R_i and $V_i R_i$ terms made it impossible to isolate their respective effects on job satisfaction in any meaningful way.

acteristics. Thus, the actual responses to the "rewards" questions are quite possibly the product of the "true" scores on these questions and the extent to which the respondent values the reward in question. Under these conditions, the job-reward measures *already* represent the interactions between the true job characteristic scores and values.¹⁷ An examination of this argument is not possible here, since the relevant information to test it consists of perceptions of individuals in the same or very similar jobs. While the perceptions of job characteristics are the appropriate data for understanding job satisfaction, a knowledge of how these relate to actual job characteristics is necessary for the formation of policy and for answering such questions as why job satisfaction is unequally distributed among the population.

A limitation on the model whose coefficients are presented in column 3 is that while it allows a ranking of the relative effects of the various values and rewards on job satisfaction, it does not permit a ranking of *dimensions*. Since job satisfaction is a function of the range of specific satisfactions and dissatisfactions that one experiences with respect to the six dimensions of work and since these "specific satisfactions" (i.e., the contribution of that dimension to overall job satisfaction) are determined by the combinations of the value and reward variables for these dimensions, it is of interest to assess the relative contribution of the six combinations to overall job satisfaction. How does one obtain a rank-ordering of dimensions? This is possible by representing the data from this model in a slightly different manner.

The strategy of this analysis is to define a new variable, say "specific satisfaction," which is weighted by the unstandardized coefficients in column 3. Satisfaction with the intrinsic dimension, for example, would be defined as: $.486 \times \text{reward} - .245 \times \text{value}$. A high value on the combination implies

high satisfaction with that dimension, a low value implies low satisfaction. (Note that in the cases where a reward has a significant effect on job satisfaction but the value does not—e.g., "financial," the specific satisfaction variable representing that dimension will be almost entirely a function of the level of reward associated with that dimension.) If overall job satisfaction is then regressed on the six specific satisfaction variables, the unstandardized coefficients will naturally be equal to 1.0 since these variables are just another way of combining the information from the value and reward variables. The relevant information from the regression of job satisfaction on the six new variables is contained in their *standardized* coefficients. These coefficients represent the standard deviations of the linear combination of values and rewards associated with each group divided by the standard deviation of the dependent variable; the relative sizes of these standardized coefficients thus indicate the relative effects of the values and rewards associated with the various dimensions on overall job satisfaction.

The standardized coefficients obtained from regressing job satisfaction on the six specific satisfaction variables are presented in column 5 of Table 3. These coefficients represent the relative effects of these six components on job satisfaction over the entire sample of workers.¹⁸ Whether workers obtain intrinsic satisfaction, for example, will have the greatest single effect on their satisfaction with their jobs as a whole. This supports recent speculation that it is the failure of workers to achieve their values with respect to the content of the task itself that is a prime cause of their dissatisfaction with their jobs (e.g., Com-

¹⁷ I am indebted to an anonymous reviewer for this observation. To argue that the values and rewards measures may be "contaminated" by each other is not an argument against equation (1), however, since this model allows for correlations among the V_i and R_i .

¹⁸ The present analysis was carried out on the total sample of workers. As always happens when individual-level data are aggregated, conclusions drawn on the basis of these aggregations may not be applicable to particular individuals. An interesting question for future research is whether the conclusions drawn regarding the relative effects of these components on job satisfaction need to be modified for particular subgroups within the population. This would imply a need for carrying out these analyses separately by sex, race, employment status, etc.

mittee on Labor and Public Welfare, 1972) and suggests the utility of recent attempts to "enlarge" and "enrich" jobs.

Whether or not workers obtain valued intrinsic rewards, however, they still may be relatively satisfied if they receive monetary compensation for their labors. The financial dimension has the second greatest effect on job satisfaction—a result which is not surprising since wages, fringe benefits and job security constitute the major sources of access to almost all goods and services as well as represent measures of the value of one's labor in a high consumption society such as the United States.

In contrast, convenience and relations with co-workers have relatively small net effects on job satisfaction for the total sample of workers. High satisfactions on these dimensions may be regarded as "bonuses" because having opportunities to attain their values with respect to these dimensions will increase workers' satisfactions with their jobs but are not the primary bases on which jobs are evaluated.

A possible alternative explanation for these results should be noted. It could be argued that the differences in the relative sizes of the coefficients reported in columns 3 and 5 of Table 3 are due to differences in the reliabilities of the various value and reward measures. It is unlikely that such an explanation is sufficient to account for these results. As a comparison of the reliabilities of these measures (Table 1) with their relative effects (column 3 of Table 3) shows, the relative effects of these measures do not correspond in any direct way to their relative reliabilities.¹⁹

These results suggest that factors associ-

ated with the intrinsic dimension have the greatest relative effects for producing overall job satisfaction. One might be tempted to conclude from this that such characteristics are most "important" for job satisfaction and that policy should be directed at improving such factors. These kinds of inferences may be misleading. The relative effects of these values and rewards on job satisfaction depend on their relative population-specific variances and, thus, these comparisons are historically specific. For example, a policy designed to improve intrinsic aspects of work could reduce the variation in intrinsic rewards; a subsequent identical study then would find that financial satisfaction has larger apparent "importance" because its variance has increased relatively, even though the causal processes remain unchanged. In fact, it may be that intrinsic work factors have become most important in producing overall job satisfaction in this country in recent years because of previous efforts to reduce the variation in financial satisfactions.

This section has examined the relationship between overall job satisfaction and the work values and perceived job characteristics associated with the various dimensions of work. The remainder of the paper will focus on the factors which influence the degree of satisfaction workers obtain from the six specific dimensions of work. A complete examination of the determinants of these types of specific satisfactions requires *both* an explanation of why people have different levels of job rewards and an explanation of why people with the same levels of rewards have different work values. The latter question will not be treated in this paper for two reasons. First, since specific satisfaction is primarily a function of the perceived level of reward associated with that dimension, it is more important for present purposes to understand why these are unequally distributed. Second, an adequate understanding of the variation in work values is very difficult to obtain with cross-sectional data, since they will change considerably as the person moves through the life cycle. (A discussion of the problems involved in studying the variation in work values with cross-sec-

¹⁹ One could, of course, examine this question directly by simply correcting the correlations among the job satisfaction, value, and reward scales for attenuation and recalculating equation (1). The measurement model underlying this procedure assumes that the errors in the items composing the scales are uncorrelated. This is a rather restrictive assumption, and it is unlikely that there may be some correlation among these items due to invalidity since these attitudinal items were obtained from the same interview. If there is any reason to suspect such correlated error, disattenuated correlations will be unstable and must be viewed with considerable caution.

tional data may be found in Kalleberg, 1975:ch. 3.)

Degree of Control and Job Rewards

The extent to which workers in an industrial society are able to obtain valued job characteristics is highly problematic. Factors associated with the industrial production process separate individuals from the forces that determine characteristics of jobs and, furthermore, such jobs are assigned on the basis of personal characteristics and are achieved by individuals competing for them. This situation is intensified in American society with its stress on economic individualism and the prevailing view that individuals have "inalienable rights" to enjoy a wide range of choice and to compete for better jobs in a free market (Wilensky and Lebeaux, 1965). Workers in such a society therefore may be assumed to seek jobs that conform to their values, though such jobs may not be available given the opportunity structure at a given point in time.

For Marx (1964), this problem of control over work was rooted in the fact that most people did not have control over the products and process of production and, thus, had little power to determine the rewards associated with their jobs. Variation in work experience was seen as a function of the economic and structural factors that determined the distribution of rewards to positions in the society, and it was assumed that rewards could be increased only by changes in these structural determinants. In line with this view, sociological theories of the quality of work experience have focused on comparative organizational and industrial contexts as the explanatory factors that account for the variation in such experience (e.g., Blauner, 1964).

While it is true that workers in an industrial society typically have little control over the distribution of rewards to positions, they do have a certain amount of control over their *attainment* of these positions. A sociological theory of the variation in the quality of work experienced by individuals should not only describe the structural factors that determine the distribution of rewards to positions; it should also explain

the factors that determine the distribution of these rewards to individuals. The latter view differs from the Marxian position in that it takes the structure of job characteristics as given and is concerned with how individuals are distributed within that structure. While a full development of this theory is clearly beyond the scope of this paper, an attempt will be made to suggest the types of factors that are operative.

At least two main sets of factors may be hypothesized to produce variation in the degree of control workers have over their attainment of job rewards in an industrial society. The first is the existing *demand* for the worker's services in the labor market. Workers with a relatively wide range of opportunities should be able to find jobs that provide greater rewards than workers whose range of choice is relatively restricted. In the present paper, this factor is measured by the unemployment rate for a worker's occupation at the time these data were collected (i.e., the first quarter of 1973).²⁰

A second factor affecting degree of control is the amount of *resources* available to the worker. Workers with more resources should have greater power with respect to obtaining job rewards than workers with fewer resources. Resources will be operationalized by four indicators: (1) the length of time the worker has been in the labor force, a proxy for the age of the worker as well as the general skills the worker has accumulated through work experience; (2) the educational attainment

²⁰ The rates for the first quarter of 1973 for the various occupational groups were: professional and technical, 2.2; managers and administrators, excluding farm, 1.5; sales workers, 3.6; clerical workers, 4.3; craftsmen and kindred workers, 3.8; operatives, 6.1; nonfarm laborers, 8.5; service workers, 5.9; farm workers, 2.4. (Source: *Employment and Earnings*, Vol. 20, January, 1974, Table A-45.) These rates are intended to measure a particular aspect of the occupational structure, namely, the structure of opportunities for employment in the various occupations. The unemployment rate is only a rough measure of this, since it includes such things as stability of employment and both voluntary and involuntary unemployment; ideally, one would want purer measures of involuntary unemployment.

of the worker, a measure of the credentials possessed by the worker and such cognitive and noncognitive characteristics related to job performance that are associated with education; (3) the worker's race, a proxy for the likelihood that the worker experienced discrimination in the labor market; (4) whether or not the worker belongs to a union or employee's association, a measure of the organizational resources available to workers to bargain for job rewards in their behalf.

The results of regressing each job-reward measure on the five degree of control measures are presented in Table 4. With respect to demand, the results in Table 4 indicate that the unemployment rate is negatively and significantly related to the attainment of intrinsic, financial and career rewards. The suggested interpretation for these negative relationships is that workers who have greater numbers of job opportunities (i.e., low unemployment) would be more likely than workers with fewer opportunities to have left jobs in which the rewards on these dimensions were perceived to be low.²¹

The relationships of the measures of resources to rewards are more complex. Workers with more experience in the labor force perceive that they have greater rewards than workers with less experience. (Years worked has no relationship to the

career dimension; older workers do not perceive their chances for a career to be greater than do younger workers.) Whites perceive that they attain higher rewards on all dimensions, except the convenience dimension, than nonwhites. Educational attainment, however, is significantly related to rewards only on the financial dimension, a result which might be explained in terms of returns on investment in human capital. That education does not increase workers' attainment of intrinsic rewards may account for why highly educated workers tend to be "over-trained," especially in the beginnings of their careers (cf. Kalleberg and Sørensen, 1973).

Workers who possess resources in the form of membership in a union or employee's association perceive that they have greater rewards with respect to the financial dimension and lower rewards with respect to the intrinsic and resource adequacy dimensions of work. Unions regulate the supply of individuals to jobs and give members more job security. They also bargain with employers for such "bread and butter" issues as wages and fringe benefits. In obtaining such rewards for their membership, however, union leaders traditionally have yielded to employers' control over certain areas of work. According to Salpukas (1974), these "management prerogatives" or nonnegotiable areas historically have included the manner in which the work is structured and the way the plant is run. These considerations may account for the lower rewards union members perceive they have on the intrinsic and resource adequacy dimensions.

The preceding is suggestive of the mechanisms involved in the relationship between degree of control and the attainment of job rewards. An elaboration of this type of reasoning may prove fruitful for the development of a sociological theory of the distribution of job rewards among various groups in the society. In the interest of the development of such a theory, it is instructive to point out the limitations of the preceding analysis. First, it has been assumed that people can maximize *all* six types of rewards. In reality, people do not attain rewards; they obtain *jobs*, which represent

²¹ A possible explanation for the lack of significant relationships between the unemployment rate and the convenience, relations with co-workers and resource adequacy dimensions may be that little information on these characteristics is available before the worker actually enters the job. Consequently, workers may not perceive that their chances for obtaining better relations with co-workers and avoiding the costs associated with inconvenience and inadequate resources are better elsewhere and would not be likely to take advantage of their alternatives for these characteristics. However, another interpretation is possible: given the way unemployment rates were assigned to occupations, it may be that the unemployment rate as utilized here simply reflects the relative availability of these rewards within the occupational structure. (The correlation between the unemployment rate and the Duncan SEI scores for the workers' occupations, for example, is $-.709$.) Thus, one could plausibly argue that the relationships observed simply reflect the fact that some rewards vary more among some occupations than among others.

Table 4. Regression Coefficients for the Effects of the Degree of Control Measures on the Six Types of Job Reward Measures: 1972-73 Quality of Employment Survey, N = 1496^a

Job Reward		Resources				Demand	
		Years Worked since 16	Education	Race ^b	Union ^c	Unemployment Rate	R ²

* p < .01.

"bundles" of job characteristics and one must often "trade-off" certain satisfactions (e.g., convenience) in order to obtain others. Second, the distinction between job characteristics and how they are perceived has been largely ignored in the above analysis. While this may be defensible in that it makes more sense to assume that people attempt to maximize their satisfaction on each dimension rather than particular job characteristics, it is clear that people attain the *characteristics* when they obtain a job. A key question for future research concerns the kinds of job characteristics that produce variation in these six dimensions of job rewards. The direct measurement of these characteristics will permit an assessment of how much of the variation in the relationship between job rewards and various social groups (defined by education, age, sex, race, etc.) is due to differences in the attainment of particular job characteristics and how much is due to differences in how these job characteristics are *evaluated*. Third, the results presented in Table 4 are only suggestive of the labor market and individual characteristics involved in the attainment of jobs. For example, labor market characteristics are only partly reflected in the level of unemployment. Such factors as the mechanisms by which jobs are distributed in various labor markets, rates of growth in particular occupations and industries, economic and business cycles, etc. are also important. Moreover, resources also include such factors as specific skills, membership in professional societies, level of information regarding job opportunities, occupational inheritance and familial factors involved in the transmission of status, etc. Such factors will be incorporated in future research designed to develop a comprehensive theory of the mechanisms which govern the matching of individuals to jobs in an industrial society.

The argument in this section has implied that rewards are *intervening* variables between workers' degree of control and their job satisfaction. To examine this argument empirically, job satisfaction was regressed first on the degree of control measures. The results of this regression are presented in the first column of Table 5. Next, job satis-

faction was regressed on the degree of control measures *and* the value and reward measures. These results are presented in column 2 of Table 5.

These results suggest that the direct effects of the degree of control measures on job satisfaction are substantially mediated by the reward variables.²² For example, while race, the unemployment rate and years in the labor force have significant effects on job satisfaction in column 1, only the latter has a significant direct effect on job satisfaction when values and rewards are controlled. It should be noted, moreover, that the coefficient for years in the labor force is sharply reduced when values and rewards are entered into the equation. That years in the labor force has a significant direct effect on job satisfaction after controlling for values and rewards may be explained by noting that this measure is highly correlated with age ($r = .90$). Older workers tend to be more satisfied with their lives in general (cf. Sheppard and Herrick, 1972) and since satisfaction with the job may reflect satisfactions experienced in other spheres of life as well,²³ this would account for this direct effect of age.

²² The causal model implied in this paper views job satisfaction as a function of values, rewards and degree of control, and rewards as functions of degree of control. While values and control may be correlated, their causal relationship is not examined here. The reduction in the effects of degree of control on job satisfaction when values and rewards are entered into the equation can best be interpreted as suggesting that rewards mediate the effects of degree of control on job satisfaction. While a portion of this reduction might also be attributed to the presence of values in the equation, the reduction due to values is minimal because: (1) values have relatively small effects on job satisfaction and (2) values and the degree of control measures are not substantially correlated (see Kalleberg, 1975).

²³ It needs to be mentioned that job satisfaction also may be a function of a whole set of nonwork-related factors unique to particular individuals, e.g., family relationships, health, etc. The present model is an attempt to explain as much of the variation in job satisfaction as can be attributed to work-related factors and is based on the assumption that one can understand the true nature of this attitude most effectively by examining such characteristics (cf. Hoppock, 1935). This focus also is useful from a policy stand-

Conclusions

This paper had two major objectives. First, it examined the variation in job satisfaction in terms of both perceived job characteristics and differences in work values. It has been demonstrated that work values have independent and significant effects on job satisfaction. Second, it suggested a framework that links the variation in job satisfaction to the factors that influence workers' attainment of job rewards.

point, since it is the factors that are associated with the workplace that are most readily open to manipulation and change. Still, it must be recognized that such factors can never fully explain the variation in the job satisfactions of individuals.

Two major lines of research are necessary to increase our understanding of the determinants of job satisfaction. First, it is important to address the question of what kinds of people have different values toward work. Variation in work values may be hypothesized to result from three major sets of social factors: (1) socialization and other types of life experiences which occur prior to the individual's entry into the labor force and which shape one's view of the importance of the various dimensions of work; (2) nonwork social roles which impose constraints and contingencies on the types of meanings that the individual can seek from the work activity; (3) work experiences which affect the mature worker's valuation of the potential rewards associ-

ated with work. For example, workers with greater numbers of dependents are more likely to value financial aspects of work, men place greater valuation on the intrinsic dimension of work than women do, etc. (see Kalleberg, 1975:ch. 3). It should be noted that an understanding of the relative effects of these determinants on the various types of work values ideally requires longitudinal panel data, since the values and their determinants may change considerably over time.

Second, it is important to understand the mechanisms by which job rewards are distributed among various social groups. This requires not only an explanation of the factors which govern the distribution of "objective" characteristics to positions, but also an understanding of the ways in which individuals attain these positions and evaluate these job characteristics. One focus of research on this issue that is needed to supplement the present analysis is a series of studies carried out within particular organizations, since the investigation of a fully elaborated theoretical model ideally should be comparative both within and between fully distinct employment situations. Data collected in this way may provide useful information on the role of individual differences in the evaluation of job characteristics, since it would be possible to compare the perceptions of workers in identical jobs. Finally, the relationship of job characteristics, job rewards and job satisfaction to occupational categories and occupational ranking systems (e.g., prestige and socioeconomic scales) needs to be examined. An understanding of why occupations are related to job satisfaction would link the study of the variation in job satisfaction to the vast literature on occupational achievement.

In conclusion, it should be noted that an understanding of the relationship of people to their work can never be accomplished using only the conceptual tools provided by sociological thought. Sociology needs to be supplemented by psychological theory in order to understand the reactions of individuals to their jobs and by economic theory to understand the structural labor market factors that govern the matching

process. Disciplinary barriers historically have constituted major barriers to a comprehensive understanding of these issues; they need to be lowered before the relationship of the individual to the job can be fully understood.

KEEPING THE FAITH OR PURSUING THE GOOD LIFE: A STUDY OF THE CONSEQUENCES OF PARTICIPATION IN THE CIVIL RIGHTS MOVEMENT *

JAMES M. FENDRICH
Florida State University

American Sociological Review 1977, Vol. 42 (February):144-157

This study examines the long-range political consequences of the earliest phase of the student movement—the civil rights movement before 1965. The research focused on a relatively homogeneous group of black and white activists who participated in demonstrations in one of the leading centers of the civil rights movement. A theoretical causal model was developed and tested using nine exogenous and intervening variables to explain adult radical political attitudes and leftist behavior. The model accounts for 45.6 percent of the variance in radical attitudes and 22.2 percent of the variance in leftist behavior. Racial differences in adult politics are explained. Tentative conclusions concerning the consequences of participation in left-wing student politics are presented.

Because of the unpredictable development and the potential for change that social movements generate, the detailed, systematic research on contemporary social movements focuses on the individual and societal antecedents in order to explain what generates discontent and what characteristics distinguish movement members from nonmembers. Although there are a few general works on the effects of movements on their external environment by Gusfield (1963), Parkin (1968) and Hobsbawm (1959) as well as unsystematic studies of the internal development of movements by Bell (1967), Holtzman (1963), Newfield (1966), Zablocki (1971) and Zinn (1964), Wilson (1973) argues there is a serious shortage of data on the consequences of social movements. This shortage is acute when attempting to understand what happens to committed members of social movements.

Killian (1964) and Sherif and Sherif

(1969) argue that what happens to a movement's members is vastly more important than the reasons they first joined a movement. The intense experience of participating in a social movement dramatically alters the subsequent social and political orientation of activists. Not only are activists personally changed, but they try to work for specific social change within society. McCarthy and Zald (1973) suggest that committed members of social movements develop careers as social change organizational intellectuals who have visions of and commitment to societal or institutional change. Similarly, Flacks (1971) states the New Left of the 1960s will begin the long march through the institutions of society as a post-industrial new working class concentrating in the knowledge and human service industries. The two major objectives of this long-range movement are: (1) to challenge the structure of power, prestige and decision making within institutions and professions and (2) to challenge the domination of institutions and professions by corporate, militarist and conservative interests and, instead, compel institutions to serve the interests of the people.

The long-range consequences that McCarthy and Zald (1973) and Flacks (1971) predict are based on the assumption of radicals' highly developed ideologi-

* An earlier draft of this paper was presented at the annual meeting of the American Sociological Association, San Francisco, August, 1975. This research was supported in part by a National Educational Institute Grant (NEG 00-3-312) and by a National Institute of Mental Health Special Fellowship (1F03 MH 58 378-01X1). I also would like to thank Hubert M. Blalock and the anonymous reviewers for comments on earlier drafts.

cal commitments to restructuring the social order. Other movements rooted in tangible self-interest may have different long-range effects. In their separate historical analysis of social movements in the United States, Ash (1972) and Gamson (1975) report the more successful movements have limited reformist goals and are related to their participants' tangible self-interest. The long-range political commitments of participants in movements with limited ideological commitments and limited movement objectives may be less radical. For example, Lipset (1950) finds Canadian farmers are radical when their economic interests are threatened; however, once the movement is successful in protecting the farmers' basic interests, the socialistic program and ideology declines. Similarly, the relatively centralist political orientation of the U.S. labor movement can be attributed to the movement's success in providing a decent standard of living and some economic security.

This study examines the adult politics of former students who were part of the early "radical probe" of the student rebellion in the 1960s (Miles, 1973). The first adult political act of black and white students was direct action to destroy the system of racial segregation. Data were gathered from black and white male activists ten years after they participated in the civil rights movement in one of the movement's leading centers; e.g., Matthews and Prothro (1966) selected the city as one of four to do an in-depth study of black political participation. Militant action started two years after the 1955 Montgomery bus boycott, when black and white students began a bus boycott with identical demands. Black community leaders were among the first to file school desegregation suits. In 1960, black and white students sat-in at lunch counters shortly after the Greensboro sit-ins. In 1963, there were demonstrations led by the Congress of Racial Equality (CORE) to desegregate public facilities that involved numerous arrests and extensive legal battles, which resulted in one major Supreme Court decision (*State of Florida vs. Adgerley*). The extent of civil rights activity can be attributed to the early development

of a group of militant black leaders (Killian and Smith, 1960) and aroused college communities.

Originally, data were gathered by mailed questionnaires from disproportionate stratified samples of activists and nonactivists.¹ Significant differences were found in adult politics within racial groups of activists and nonactivists (Fendrich, 1976). Results reported here will focus on the variance to be explained among black and white activists. This approach has the advantages of a natural experiment, i.e., black and white activists participating in the same political events in one community and demanding, through their civil disobedience, the end of segregation in the South. The control reduces many sources of error that might account for differences in adult politics. Twenty-eight white and 72 black activists returned questionnaires. For both groups, activists were more likely to respond to the questionnaire than members of control groups.² Two sources of bias probably affect the results. The first is the quality of the sampling frames, i.e., the responses are biased toward those respondents for whom the university records were the most accurate.³ In the white sample,

¹ For blacks, questionnaires were sent to those arrested during demonstrations (50%), student government leaders (81%) and a systematic sample of undergraduates (11%). Due to a lack of research funds, 50 questionnaires were sent to each of three groups of white demonstrators, student government leaders and a random sample of university alumni. In cases of overlap between the different strata, those who demonstrated were considered activists.

² The response rates for the whites were: 73% for activists, 69% for student government and 72% for the random sample. The black response rates were: 38% for those arrested, 37% for student government and 36% for the systematic sample. The percentages for whites are substantially better and the percentages for blacks are about the same as a second-wave response rate of a well funded five-year follow-up of college students by El-Khawas and Bisconti (1974). The analysis was limited to 87 activists that provided information.

³ The major reason for the differences in black and white response rates is the quality of the sampling frames. At the predominantly white university, the alumni office was able to provide current addresses for over 80 percent of the former students. The black university did not

key leaders of the student protest were also less likely to respond.⁴

The major questions are: (1) To what extent have activists maintained their political commitments? (2) Are there major differences in the adult politics of black and white civil rights activists? (3) If there are differences, can the relative level of left-wing political participation be explained? In order to answer these questions, a recursive causal model is developed. The model is derived from existing theory, established empirical relationships and assumptions concerning the causal ordering of the variables.

SPECIFICATION OF THE THEORETICAL MODEL

A recursive model explains variance in the endogenous variables of political attitudes and behavior. Path analysis (Duncan, 1966) proves useful when studying processes of groups whose experiences are traced over time. Exogenous variables measuring pre-college, college and post-college experiences are expected to have direct and indirect effects on adult politics. The variables in the model are: (X_1) adult protest behavior; (X_2) adult radical political attitudes; (X_3) occupational values; (X_4) socioeconomic status; (X_5) family obligations; (X_6) career choice; (X_7) graduate education; (X_8) academic ability; (X_9) major in college; (X_{10}) parental socioeconomic status; (X_{11}) race. The simultaneous linear equations for the model are:

$$X_{11} = e_{11} \quad (1)$$

$$X_{10} = b_{10,11}X_{11} + e_{10} \quad (2)$$

$$X_9 = b_{9,11}X_{11} + b_{9,10}X_{10} + e_9 \quad (3)$$

$$X_8 = b_{8,11}X_{11} + b_{8,10}X_{10} + e_8 \quad (4)$$

$$X_7 = b_{7,11}X_{11} + b_{7,10}X_{10} + b_{79}X_9 + b_{78}X_8 + e_7 \quad (5)$$

have the same resources for keeping good records. The majority of addresses for the black sample were obtained from the registrar's office files. Particularly for the black sample, the responses probably are biased toward the less geographically mobile.

⁴Key leaders were determined through interviews with faculty and staff members who had observed the student protest closely. Four out of seven white student leaders did not respond. Six of eleven key black leaders did not respond.

$$X_6 = b_{6,11}X_{11} + b_{69}X_9 + b_{67}X_7 + e_6 \quad (6)$$

$$X_5 = b_{5,11}X_{11} + b_{59}X_9 + b_{57}X_7 + e_5 \quad (7)$$

$$X_4 = b_{4,11}X_{11} + b_{4,10}X_{10} + b_{47}X_7 + b_{46}X_6 + e_4 \quad (8)$$

$$X_3 = b_{3,11}X_{11} + b_{39}X_9 + b_{37}X_7 + b_{36}X_6 + b_{34}X_4 + e_3 \quad (9)$$

$$X_2 = b_{2,11}X_{11} + b_{29}X_9 + b_{27}X_7 + b_{26}X_6 + b_{25}X_5 + b_{24}X_4 + b_{23}X_3 + e_2 \quad (10)$$

$$X_1 = b_{1,11}X_{11} + b_{19}X_9 + b_{17}X_7 + b_{16}X_6 + b_{15}X_5 + b_{14}X_4 + b_{13}X_3 + b_{12}X_2 + e_1 \quad (11)$$

Since the theory is primarily concerned with explaining adult politics, the theoretical discussion will begin with equations (10) and (11). The same direct causal links are expected for both variables, except that radical attitudes also are considered an exogenous variable for leftist behavior.

Race is considered an indirect indicator of ideological commitment among civil rights activists. While blacks and whites were idealistic and committed to the movement (Demerath et al., 1971; Orum, 1973; Warren, 1965), important differences separated them. The self and collective interests of aspiring middle-class blacks were involved (Miles, 1973). They expected to benefit directly from changes the civil rights movement achieved. The Geschwenders (1973) found that Southern black students were motivated by particular types of relative deprivation to participate in the civil rights movement. Relative deprivation is defined as the discrepancy between value expectations (the goals and conditions of life to which one feels entitled) and value capabilities (the goods and conditions one feels capable of getting and keeping). Three types of relative deprivation were found to be related to levels of student participation in civil rights protest—collective black aspirational deprivation, anticipated future aspirational deprivation and reference group satisfaction. Blacks who were the most extensively involved in the civil rights protest felt the greatest discrepancies for blacks collectively at their current position and also felt that this discrepancy would exist in the future. When comparing themselves to other blacks, college activists considered themselves better off. In short, blacks were committed to participate in the

politics of disruption to reduce the discrepancy in value expectations and value capabilities.

The ideological commitment for whites to participate in the civil rights movement was different. They had nothing to gain materially, individually or collectively, from their participation. In contrast to the popular assumption that guilt feelings were the motivational base for white participation, Demerath et al. (1971) found a different pattern for whites who participated in the civil rights movement. Analyzing self-reports of white activists, they found a diffused motivational theme of other-oriented humanism. Comparing white activists to a control group of Wisconsin students who did not participate in the movement, they found no differences on attitudes toward civil rights; however, the white civil rights activists were distinctive in their tendency to be concerned about more political issues in a more left-wing direction than liberal Wisconsin students. They were primed to become involved in social movements that held some promise of moving the society in more equalitarian, democratic and socialistic directions. At that time, the civil rights movement was the only available outlet for their ideological commitments. As Demerath et al. (1971:36) commented, ". . . the civil rights movement offered a structured political identity to those with broad-ranging political concerns." The differences in ideological commitment can be summarized as the differences in interest group politics versus radical ideological commitments to restructure societal institutions.

There are additional causal links that explain adult politics either directly or indirectly through intervening paths. Studies have shown that students majoring in liberal arts, particularly the social sciences and humanities, are further to the left politically than other college majors (Braungart and Braungart, 1974; Flacks, 1967; Lipset, 1972). This difference is expected to persist into adulthood. Post-college experiences also are expected to affect adult politics. Although evidence of the influence of graduate training as a liberalizing or radicalizing experience is mixed (Meier and Orzen,

1971; Lipset, 1971; Kornberg and Brehm, 1971), it is considered an important opportunity to reinforce and develop earlier political commitments because of prolonged exposure to leftist campus politics during the 1960s and because of the further development of knowledge and skills, particularly in liberal arts programs, to critically assess societal institutions.

Research suggests that college graduates who have pursued careers in the public sector of the economy, especially the rapidly expanding knowledge and human service industries, are more likely to have leftist commitments than those who enter the private sector of the economy (Fendrich and Tarleau, 1973; Krauss, 1974). Although family obligations can be a constraining influence on protest politics (Almond and Verba, 1963), former activists can exercise the choice of remaining single or deciding not to have children, thereby not subjecting themselves to the constraining influence of family obligations. As a result, they will be more politically active in political protest as adults.

The higher socioeconomic status (SES) activists are expected to be more radical than lower-SES activists independent of the separate effects of graduate education and occupational prestige associated with jobs in the knowledge and human service industries. Because of their structural location in various institutional sectors, higher-SES activists are more strategically located to witness the "business as usual" orientation within institutions that fosters institutional racism, the dominance of elitist interest groups in policy considerations, and the entrenched unwillingness to change institutional objectives. Their achieved status does not moderate their politics, but it does contribute to their political alienation. For example, young higher-SES blacks are more militant and alienated than those with lower SES (Matthews and Prothro, 1966; Michigan Survey Research Center, 1973). For white activists, the effects are similar. Those with higher SES are in a better position to see the malfunctioning of decision making within established institutions.

The last variable expected to influence both political attitudes and behavior is oc-

cupational values. Rosenberg (1957) found that college students develop distinctive occupational values. He discovered three major value clusters associated with career expectations—self-expressive values, people-oriented values and extrinsic reward orientations, i.e., high value placed on money, prestige and security. McFalls and Gallagher (1975) found a strong association between occupational values and student left-wing politics, particularly the low value leftists placed on extrinsic rewards. This relationship was expected to continue into adulthood.⁵ Those activists furthest to the left as adults were expected to place a high value on helping people and self-expression and low value on extrinsic rewards.

The final variable expected to influence protest behavior directly is radical political attitudes. Studies ranging from *The American Voter* (Campbell et al., 1960) to Goldberg (1971) indicate that political attitudes are important determinants of behavior. Although the strength of the relationship between attitudes and behavior may be partly spurious—i.e., due to the indirect effects of previous variables—political attitudes are expected to have a separate direct effect on political behavior. Two variables not included in equations (10) and (11)—parental SES and academic ability—are considered to have only indirect effects on the endogenous variables through intervening causal linkages.

The remaining equations in the model concern the intervening variables. Because of past and current discrimination (Blauener, 1972), race is expected to be a major determinant of parental SES. Race and parental SES are expected to have direct effects on both academic major and academic ability. Whites and those from higher-SES families are expected to be more likely to major in the social sciences and liberal arts and to have higher grade point averages. Because of ideological com-

mitments, the importance of financial support, the necessity of advanced degrees for occupations in the knowledge and human service industries and demonstrated academic excellence, all four causal antecedents are expected to influence graduate education (Fichter, 1964).

Only three variables are considered to have direct causal effects on career choice. The decision to choose a career in the knowledge and human service industries is influenced by humanitarian or leftist political commitments, majoring in the social sciences and having attended graduate or professional schools. The choice of remaining single or marrying but not having children is influenced by the degree of ideological commitment to radically restructuring the social order. Alternatives to the nuclear family also are expected to be higher among those who majored in the social sciences or attended graduate school.

Four variables have direct effects on the activists' SES. Those with the strongest ideological commitment are not expected to pursue monetary success and prestige and, therefore, have lower SES. The socioeconomic status of the respondents is transmitted across generations with parental SES affecting the current status of the respondent (Blau and Duncan, 1967). Graduate education is one of the primary criteria for SES. Those who have chosen careers in the knowledge and human service industries are expected to have lower SES. Even though they are likely to hold advanced degrees, their occupations are not any more prestigious than many of those in private sector occupations and, more importantly, there are restrictive wage ceilings in the public sector occupations they have chosen.

Finally, four causal antecedents have direct effects on occupational values. White activists are expected to value extrinsic rewards the least and to emphasize humanitarian and self-expression values. Both the initial commitment and the intellectual exposure to the social sciences is related to the same clustering of occupational values. Socialization emphasizing professionalism in graduate education is expected to have an independent effect on occupational values.

⁵ This variable was the most difficult to order in the causal model. Because of the limitations of the after-only research design and the expected effects of post-college experiences on career values, it was considered an endogenous variable immediately prior to adult politics.

OPERATIONALIZATION OF THE MODEL

Protest Behavior (X_1)—Operationally, this variable measures the extent of participation in political acts demanding reform or social change. Originally a five-item scale was developed to measure political efficacy. Three of the five items were selected to measure protest behavior: (1) organizational work in political programs and campaigns;⁶ (2) participation in demonstrations; (3) participation in any form of illegal political activity. The responses ranged from "frequently" to "never." Exploratory factor analysis was used to analyze the five items for each sample. The three items above emerged as the principal component. The scores ranged from 3 to 12. The higher the score the greater the participation.

Radical Political Attitudes (X_2)—Conceptually, this refers to the left-wing political sentiments of the former activists. A 14-item radicalism-conservatism Likert scale developed by Nettler and Huffman (1957) measured radical attitudes. In general, the scale measured attitudes concerning socialist versus capitalist economic and political programs.⁷ The scale was found to be both reliable and valid by its authors. The responses ranged from "strongly agree" to "strongly disagree." The scores ranged from 14 to 70. The higher the score, the more radical the political attitudes.

Occupational Values (X_3)—Rosenberg (1957) developed a 10-item occupational value scale measuring three clusters of values: self-expression values, people-ori-

ented values and extrinsic reward values. Exploratory factor analysis was used to verify the three separate value clusters for each sample. Only two factors emerged, one consisting of the three extrinsic reward measures—money, prestige and security—and a second general factor that included the remaining items. Only the unambiguous extrinsic reward value cluster was used to measure occupational values. Each item had three responses: high, medium and low. The scores ranged from 3 to 9. The higher the score the greater the emphasis placed on extrinsic rewards.

Socioeconomic Status (X_4)—A composite measure of education, occupation and income scores was used to measure SES. The selected procedure was developed by Nam (1963) for the U.S. Census Bureau. The range of scores was from 0 to 100 with higher scores indicating higher SES.

Family Responsibilities (X_5)—Operationally, respondents were asked to indicate the extent of family obligations, varying from being single to being married and having children. The range of scores was from 1 to 3 with higher scores indicating more obligations.

Career Choice (X_6)—This refers to occupational pursuits after college. Occupations were classified along a continuum that represented those work organizations that emphasized the profit motive at one extreme and those work settings that were knowledge and human service oriented at the other extreme. Operationally, there were five categories: (1) proprietors, managers, officials and salesmen in the private sector of the economy; (2) private practice professionals, e.g., doctors, lawyers, dentists, etc.; (3) government workers; (4) academic professionals; (5) those in social service and creative occupations, i.e., writers, journalists, social workers, full-time activists, etc.⁸

⁶ This particular item, at face value, does not seem to be a good example of leftist behavior; however, inspection of the questionnaires revealed that former activists were supporting either the liberal left-wing of the Democratic Party or local leftist reform candidates and programs, e.g., New Democratic Party or community action leagues.

⁷ A few examples of items in the scale are: (1) In a socialist system the worker maintains his dignity and self-respect, while under capitalism he is just a tool or instrument to be exploited. (2) No one should be allowed to earn more than \$25,000 a year "take-home" income. (3) Profits of the great industries should be rigidly controlled by the federal government. (4) It is up to the government to make sure that everyone has a secure job and a good standard of living.

⁸ Career choice, as well as some other measures, must be considered ordinal rather than interval or ratio measures. Although interval measures are assumed in regression analysis, Reynolds (1974) has found that ordinal measures can be used successfully in causal analysis if there are an adequate number of categories,

Graduate Education (X_7)—This variable measures the amount of education beyond an undergraduate degree. The responses ranged from "not attending graduate school" to "receiving two advanced degrees." The range of scores was from 0 to 8. The higher the scores the more extensive was the graduate education.

Academic Ability (X_8)—This variable was measured by the self-reported undergraduate grade point average.

Academic Major (X_9)—Operationally this variable measures major in college. All majors were collapsed into three categories: (1) non-arts and science major; (2) arts and science major except for social science; (3) social science majors.

Parental Socioeconomic Status (X_{10})—This variable was measured the same as respondent SES.

Race (X_{11})—Operationally, this is a dichotomous variable that distinguishes between the black and white respondents. A score of 0 identified black respondents and 1 identified white respondents.

RESEARCH FINDINGS

A series of criteria are used to test the adequacy of the theoretical model and to develop a more parsimonious restrictive model from the data.⁹ The model is tested for its general goodness of fit using maximum likelihood estimation procedures outlined by Land (1973). The correlation matrix also is reconstructed from the path

the responses are not highly skewed and control variables are measured with as much refinement as the independent and dependent variables.

⁹ One of the reviewers of the manuscript encouraged the author to weaken the assumptions in the model and test alternatives that would allow reciprocal causation, particularly between extrinsic rewards, radical attitudes and protest behavior. Utilizing two-stage least squares, different sets of static simultaneous equation models were examined. In every case, the alternative causal paths did not meet the criterion of explaining at least one percent of the variance in endogenous variables. The predicted values of the second stage also produced extreme values of path coefficients. This later result was due to multicollinearity. The predicted values for the second stage were functions of the variable race and highly intercorrelated with each other.

model to discover whether there are significant deviations from the original correlations. Since the research focused primarily on attempting to explain variance in endogenous variables, each path coefficient was examined to determine if it explained, at a minimum, one percent of the variance in the endogenous variables.¹⁰ A restricted model was developed from a fully recursive model based on this last criterion and was tested also for its general goodness of fit and its ability to reproduce the original correlation matrix.

Table 1 reports the path coefficients and the coefficients of determination for both the theoretical and restricted models. The goodness-of-fit test revealed the theoretical model was an adequate model for the existing data. The chi-square value was 8.567. With 17 degrees of freedom, the relationship between observed and expected values was not significant indicating the model was consistent with the empirical relationships. The theoretical model was somewhat less successful in reproducing the original correlations. Small variations between actual and predicted correlations of less than .05 were attributed to measurement error and were not considered significant. The predicted correlation matrix reproduced 47 out of 55 correlations within this range. The discrepancies greater than .05 were:

$r_{2.10} = .089$	$r_{45} = .068$
$r_{35} = .076$	$r_{48} = .159$
$r_{38} = .051$	$r_{68} = .187$
$r_{3.10} = .089$	$r_{89} = .091$

The deviations between academic ability and respondent SES (r_{48}) and academic ability and career choice (r_{68}) are substantial.

Based on the criterion of explaining variance, the theoretical model was revised. Eleven paths were dropped from the model and one was added, creating a more parsimonious model.

¹⁰ This criterion is different from the criterion of statistical significance, e.g., the path coefficient being at least twice the standard error. Since the major objective of the research was to explain variation in adult politics, the criterion of variance explained was chosen.

X ₃ Extrinsic Rewards	-.364	-.363
X ₂ Radical Attitudes	.006	—
Coefficient of Determination	(.230)	(.222)

monious model. The eleven paths dropped from the model were:

p9.11 = .093	p36 = .052
p79 = .106	p17 = -.046
p78 = .014	p16 = -.022
p69 = -.069	p14 = .084
p39 = .014	p12 = .006

The last four paths are related directly to the endogenous variable of protest behavior. The one path that was added was p48 = .138. Academic ability as reflected in self reports of college grade point averages has a direct effect on the respondents' socioeconomic status. The goodness of fit is slightly better for the restricted model. The chi-square is 7.135 with 27 degrees of freedom. Given the fewer number of predicted paths, it is more difficult to reconstruct the original correlations. Table 2 presents the observed correlations and the reconstructed correlation matrix. Forty-five of the predicted correlations were within .05 of the observed values. The deviations from the observed values, however, were smaller than the original theoretical model. The ten correlations that deviated by more than .05 were:

r15 = .057	r38 = .064
r2.10 = .097	r45 = .074
r35 = .082	r68 = .075
r3.10 = .059	r89 = .079
r3.11 = .060	r79 = .080

The restricted model is an improvement and has the added benefit of being more efficient or parsimonious because fewer path coefficients are needed to explain the same amount of variance in the endogenous variables. Since the primary research objective is to account for the variance in adult politics of the former black and white civil rights activists, the remaining discussion of the findings will focus on the direct paths to radical political attitudes and protest behavior in the restricted model.

Six paths are directly related to radical attitudes. Race (.384), major in college (.158), career choice (.162), family obligations (-.193), respondent SES (.231) and extrinsic rewards (.167) accounted for about 46 percent of the variance in socialist versus capitalist attitudes toward economic and political policies. Race by itself explains most of the variance—34 percent. The remaining five variables explain between one and three percent of the vari-

ance. Former white activists were the most radical as adults; however, those former activists who majored in the social sciences, chose careers in the knowledge and human service industries, were either single or married but without children, had higher SES and valued extrinsic rewards the least also held radical political attitudes.

The restricted model has four direct paths related to protest behavior. They are race (.070), major in college (.126), family obligations (— .110) and extrinsic rewards (— .363). Together, they explained 22 percent of the variance.¹¹ The two variables which have the largest direct effects are race and extrinsic rewards, which explain 9 and 11 percent of the variance, respectively. Those adults who are most likely to continue to engage in protest politics are whites, former social science majors, single or married activists without children and those who least value extrinsic rewards of money, prestige and security. These are strong findings given the various sources of measurement error, the necessity of using indirect indicators of ideological commitment, and the possible exclusion of significant variables contributing to the unexplained variance.

Besides the direct effects of the variables on adult politics, there are also the indirect effects. Space does not allow a presentation and discussion of the individual and total indirect effects which can be computed from the available data. In general, variables that are intercorrelated and have large direct effects also have large indirect effects, e.g., student activism, which has strong indirect effects on the dependent variables.

In a separate analysis (Fendrich, 1976), the same variables were used to explore differences among white activists and non-activists and among black activists and non-activists. The research objective was to try to explain the variance in adult politics

¹¹ The major reason why the model is not as successful in predicting protest politics is the low precision of the endogenous variable when compared to the attitude measure. More detailed questions were considered in the preparation of the questionnaire, but it was decided these questions would have a major effect in reducing the response rate.

among racially homogeneous yet politically heterogeneous groups. The variables explained substantially more variance among the politically heterogeneous whites. For whites, the coefficients of determination (R^2) were .600 for radical attitudes and .421 for protest behavior. The coefficients for blacks were .122 and .247, respectively. The path models were better at predicting adult politics because there was more variation to be explained in the dependent variables, i.e., whites who were not active in protest politics as students are much more moderate or conservative. Stated somewhat differently, the within-racial group variance in adult politics is greater than that between-racial group variance for activists. Nevertheless, the results reveal important differences among the activists.

The two variables that have the largest effects are the race of the respondent and the value placed on extrinsic rewards. The race variable has strong direct and indirect effects. Race is considered an indirect indicator of ideological commitment. This assumption is consistent with the Geschwenders' (1973) research on the same black students. They found black activists were motivated to participate in the civil rights protest by feelings of relative deprivation. Demerath et al. (1971) and Von Eschen et al. (1971) found that white students who participated in the early phase of the civil rights movement were motivated by a leftist political ideology and humanistic commitments. Thus, there is empirical support for using race as an indirect indicator of leftist ideological commitment. The assumption is supported also by the subsequent findings that former black activists place higher value on extrinsic rewards and are more likely than whites to seek careers in the private sector of the economy that offer the rewards of money, prestige and security.

The extent of the differences in adult politics is revealed in descriptive statistics. The former activists were asked to identify themselves politically on a continuum from right to left. For whites, 21 percent are political moderates, 25 percent are liberals and 54 percent are radicals. For blacks, 13 percent are political conservatives, 52 per-

cent are moderates, 25 percent are liberal and 10 percent are radicals. Moreover, 75 percent of the whites participated in political demonstrations as adults compared to 47 percent of the blacks; and 43 percent of the whites engage in politically illegal protest as adults compared to 19 percent of the blacks. Whites, as adults, are clearly further to the left ideologically and more willing to continue to engage in protest politics.

If race is a good indicator of the initial ideological commitment to join a social movement, then it would be incorrect to conclude that the political commitments of black civil rights activists have been radically altered. Put more bluntly, it would be incorrect to assume black civil rights activists were coopted as adults. Their commitments as adults are consistent with their earlier beliefs. They fought for the right to enter the mainstream of American society (Warren, 1966) and, because of the relative success of the movement for young college-educated blacks (Pettigrew, 1975), they are now able to reap the benefits of that struggle. They are still committed to the specific issue of civil rights. Like members of successful unions, they can be mobilized to support left-of-center candidates and issues when their own interests are at stake. In contrast, the majority of former white activists are self-professed radicals. Whites are further to the left ideologically and are actively trying to bring about basic structural changes through social movement organizations and as social change organizational intellectuals.

Extrinsic rewards independent of the effects of race also had a strong effect on adult politics. Those former activists who are free of strong commitments to extrinsic rewards can pursue their political objectives. On the other hand, activists who place a high value on money, prestige and security cannot afford to participate in leftist politics as adults because of the risk of negative sanctions from peers and employers. There is no good measure for the positive career values associated with adult leftist politics. Activists who have maintained their political commitments probably are motivated by career values that stress

change and modification of the social structure (McCarthy and Zald, 1973; Flacks, 1971), i.e., the adult activists want to work in organizations that stress moving the social institutions in a more democratic and socialist direction.

CONCLUSIONS

Three tentative conclusions can be drawn from the research findings. First, persons active in protest politics who were active when they were college students are further to the left politically and more active in protest politics as adults. This indicates that adults who sustain commitments to a political movement must develop such commitments in their youth. This finding is consistent with generational conflict theory (Fendrich, 1974). Second, for adults to sustain commitments to radical leftist movements, they must be motivated initially by strong ideological commitments that extend beyond interest-group politics. This finding is based on the black-white differences. If social movement participants are motivated primarily for personal and collective gain, e.g., relative deprivation, they can become more politically moderate as adults if the movement is successful in opening opportunities for upward mobility. Finally, for adults, a strong ideological commitment to social change in a leftist direction needs to be supported by a personal commitment not to pursue career objectives for the sake of extrinsic rewards of more money, prestige and security.

Thus, three conditions were discovered that help to explain adult involvement in left-wing political movements. Adults who are active developed a high level of political consciousness and participation in their youth. They were motivated by ideological rather than pragmatic values. They need to remain free of both objective and subjective constraints that can inhibit their adult politics. These findings and conclusions are based on a small fraction of the student activists in the civil rights movement. Before they can be considered valid generalizations to explain the persistence of left-wing movement participation, additional empirical research and theoretical development is necessary.

One final point concerns the use of the multivariate model. There is growing opposition to the use of multivariate analysis in sociology. Both the immediate past Presidents of the American Sociological Association, Coser (1975), and Lee (1975), have expressed doubts about the use of these techniques. While space is not available to do full justice to their position, they generally argue that multivariate models, while rigorous, are not very illuminating because such techniques direct attention away from important sociological issues. This criticism is not necessarily valid. Multivariate analysis can be a means to address politically and socially relevant questions. Indeed, radical economics which uses essentially the same techniques is gaining widely based scholarly respectability (Lekachman, 1976). It also should be mentioned that multivariate model building and analysis reveal the modest state of accumulated knowledge within the discipline more critically than previous, less rigorous procedures.

A MODEST TEST OF AN IMMODEST THEORY: THE FUNCTIONAL THEORY OF STRATIFICATION *

LÉONARD BROOM

ROBERT G. CUSHING

The Australian National University

American Sociological Review 1977, Vol. 42 (February):157-169

Two hypothesis relating responsibility, reward and performance were designed to test the Davis and Moore functional theory of stratification. Large companies in the private sector of the United States economy were selected as the source of empirical evidence to test the theory. The data base was thought to be favorable to positive findings. The responsibility variable was measured by company assets, reward was measured by total compensation of the chief executive officer, and performance was indexed by several measures of growth and profitability. Over 700 of the largest companies in the United States were grouped into sixteen relatively homogenous business activity types in order to control for (1) scarcities of qualified incumbents, (2) structural differences between industries and (3) market conditions. The results provide limited evidence of a relationship between magnitude of responsibility (functional importance) and executive compensation (reward). No support was found for a hypothesized relationship between company performance, however measured, and executive compensation. Taken as a whole, the results do not confirm the functional theory.

The so-called functional theory of stratification as formulated by Davis and/or Moore (Davis, 1942; 1948; 1953; Davis and Moore, 1945; Moore, 1953; 1963)

has drawn attention to important issues for the study of social stratification. The debate, which has stretched over a generation, has been characterized by a sense that the writers were dealing with matters worthy of argument, although the brief and abstract form in which the theory was presented originally made it susceptible to diverse interpretations (Wesolowski, 1962:

* We are grateful to Parker C. Fielder for guiding us to a relatively tractable data set. We thank the *ASR* reviewers for thoughtful and constructive comments.

28). Despite the liveliness (and sometimes the heat) of the controversy, there has been little progress towards specifying a test of the theory (see Huaco, 1966). It is tempting to say that the longevity of the theory is related to its inaccessibility to empirical verification.

The present paper is a modest attempt to test a falsifiable version of the theory. We do not propose to investigate generalizations that pretend to be good for all sectors of all societies for all time. If doubt is cast on the theory restated in an acceptably rigorous and verifiable form and tested in a limited context, it will be incumbent on the defendants of the theory to restate it in less vulnerable form or to show why the test is incompetent or irrelevant, i.e., a unique exception. On the other hand, if the findings support the theory, the theory is supported only for the situation under scrutiny, although its plausibility score should be improved and the requirements for a more powerful test might be made more specific.

The Davis and Moore Formulation

The Davis and Moore theory (Davis and Moore, 1945:243; Davis, 1953:394-5; Moore, 1963:15) is addressed to a deceptively simple question: Why do different social positions in a social system carry different degrees of prestige and reward? Their answer is also deceptively and anthropomorphically simple: "Social inequality is . . . an unconsciously evolved device by which societies insure that the most important positions are conscientiously filled by the most qualified persons" (Davis and Moore, 1945:243). Therefore, stratification is a universal necessity for system survival. The specification of *most* qualified as opposed to sufficiently qualified is a needless burden on the theory, but it is not taken seriously and need not detain the present discussion (Wesolowski, 1962:28-9).

It is important to note that the theory focuses on the social positions in a given social system and on the type of individuals who occupy those positions at any given time, not on specific persons. Since not all

social positions have equally pleasant tasks, or are equally important to societal survival, or require the same amount of talent or training for their competent performance, "it does make a great deal of difference who gets into which positions" (Davis and Moore, 1945:243). Thus, and again anthropomorphically, a society must "instill in the proper individuals the desire to fill certain positions, and, once in these positions, the desire to perform the duties attached to them" (1945:242). This is to be accomplished by a system of rewards as inducements. The rewards must be differentially distributed to social positions according to the importance of the positions *and* according to the scarcity of qualified personnel available for those positions in order to guarantee that "less essential positions do not compete successfully with more essential ones for competent personnel" (1945:243). Attempts to explore aspects of the theory empirically have found the measurement of functional importance problematic and the results have been equivocal (Abrahamson, 1973a; 1973b; 1974; Grandjean and Bean, 1975; Harris, 1967; Land, 1970; Leavy, 1974; Lopreato and Lewis, 1963; Stinchcombe, 1963; Stinchcombe and Harris, 1969; Vanfossen and Rhodes, 1974).

Toward a Test of the Davis and Moore Formulation

Davis and Moore imply a simple causal chain between the functional importance of social positions and the rewards, qualifications and contributions to system survival of incumbents in those positions. Since we cannot deal with relative uniqueness, the first clue Davis and Moore offer to operationalize functional importance, we accept their second clue and measure functional importance by "the degree to which other positions are dependent on the one in question" (Davis and Moore, 1945:244n). The scarcity of qualified incumbents influences both the relationship between functional importance and the distribution of rewards and the relationship between distribution of rewards and the relationship between distribution of re-

wards and the distribution of qualified personnel.

Although they intended their theory "to explain, in functional terms, the universal necessity which calls forth stratification in *any* social system" (Davis and Moore, 1945:242, our italics), they fixate on positions unique to societal survival in their discussion of what they mean by functional importance and performance. Non-survival represents ultimate failure, but how does one assess whether the role prescriptions of a unique position have been carried out in a way to ensure societal survival? The failed monarch or president or general might have performed uniquely well, but the society may have collapsed for reasons beyond the control of mortal persons. Or the performance might have been uniquely bad, but the society tottered on despite that fact.

It is difficult to see how to use the survival criterion to test the theory. At first glance, survival seems easy and obvious to verify—but survival for how long, in what form, and ascribed to what sequence of episodes and human actions? The histories of societies are interlacings of one-time events of inordinate complexity, and there can be no sufficient and necessary explanation for nonrecurrent phenomena. Since monarchs are dethroned, presidents untaped and generals cashiered for reasons both related and unrelated to their qualifications or performance, a collection of such unique positions and their occupants does not make a data set. If we shift emphasis from actual survival to potential for survival in order to expand the data set, how is relative potential survival to be measured: by gross national product, by morbidity and mortality rates (inverted), by literacy, by degree of industrialization, by cost of living (inverted), by standard of living, by energy resources (consumed or preserved), by a composite index of all or some of the above? The methodological difficulties that are inherent in the thesis when societal survival is a focus of interest may be surmountable, but we despair of making societal comparisons of rewards associated with functionally unique positions. Waiting for societies to expire may

hold out promise in the present world climate, but we prefer to seek less apocalyptic criteria for a test. We propose to substitute the testable notion of performance for the untestable notion of survival. This substitution would be acceptable to Moore:

The explanation presented here reiterates the thesis that "functional differentiation" of positions will inevitably entail unequal rewards—and adds the thesis that *differences in performance must be expected to be and will be differentially valued*. (Moore, 1963:15, our italics)

In discussing the determinants of positional rank, Davis and Moore come closest to a testable statement of the theory:

In general those positions convey the best reward, and hence have the highest rank, which (a) have the greatest importance for society and (b) require the greatest training or talent. (Davis and Moore 1945: 243)

It is clear that such a statement is intended not as a static description of the state of a system but as a dynamic statement of causal connections. A direct observed relationship between functional importance and reward would be explained in terms of the necessity for motivating qualified persons to fill and discharge important positions conscientiously. Even if the relevant variables could be specified and measured, cross-sectional analysis cannot directly test this dynamic causal principle.

Nevertheless, an indirect test of the causal principle is apparent. If, controlling for scarcity, the expected relationships (between the functional importance of positions and rewards, between rewards and qualifications, and between qualifications and performance) are not observed, at a given point in time, then the necessary preconditions for the functional explanation do not exist. The implications of such a result for the theory are obvious, and the test can be determined by cross-sectional analysis. However, since the causal mechanism, is not dealt with directly in a cross-sectional study, a positive result may add to the plausibility of the theory but does not rule out alternative explanations for why some positions are highly rewarded.

An exhaustive test of the theory would

require measures of differential functional importance, differential scarcity and distribution of qualified personnel, the differential distribution of rewards, and the differential performance of incumbents. We doubt that any single test can deal with all these variables simultaneously.

Criteria for Selecting Functional Areas and Units of Analysis

A straightforward empirical test of the theory requires the identification of one or more functional areas with reasonably clear criteria for and accessible indicators of responsibility, reward and performance. We do not know how to estimate relative functional importance of tasks performed in different spheres of human endeavor. The nature of the dependencies are different. Therefore, comparisons should be made within rather than between kinds of functions. Another reason for this restriction is that the reward side of the equation may be confounded if cases are drawn from diverse fields. For example, the rewards for the clergyman, artist, teacher and politician very well may be different in kind, and the comparisons necessary to test the theory could not be made even in the unlikely event that there was agreement about the relative functional importance of these several fields of endeavor.

If the problem of societal survival is not a profitable case and if unique positions are not available for analysis, what kind of data can be used to test the theory? The positions to be examined should carry high and measurable responsibility (i.e., they should be functionally important for something), there should be some way to assess performance and they should have variable rewards. Such positions should occur in the very kind of society that the adversaries of the functional theory grumble about, i.e., they should be positions gained in competition, and the positions should be rewarded for activities involving struggle for advantage. Senior management positions in capitalistic industrial organizations come as close to satisfying these criteria as any. It is hard to imagine a category of positions more likely to yield

support for the theory (Davis, 1948:369-70; Wesolowski, 1962:31).

We have elected to focus on a sample of large, publicly held companies within the private sector of the U.S. economic system. United States law requires such companies to make available to regulatory agencies, to stockholders and to other interested or curious persons, information that can be constructed into indicators of the magnitude of responsibility represented in the company, of the company's degree of success and of the kind and amount of rewards afforded senior executives. The data are presented in annual reports to stockholders and in requests for proxies at the time shareholder meetings are announced. We have not yet fully explored the possibility of securing similarly detailed information for companies in other countries, but we know that many countries do not require similar disclosure. It goes without saying that companies anywhere are disinclined to disclose publicly anything more than they must. Companies closely held by a few owners are not available for analysis because they are not required to expose themselves in this way and do not.

Research Design

Units of analysis. There are three possible kinds of scarcity: of personnel, of rewards and of positions, and we suggest that of the three only highly valued positions are truly scarce in mature industrial societies (Huaco, 1966:238). If there were a scarcity of executive talent, that scarcity would probably be constant within business activity areas in the sense that the pool of potential incumbents is the same for all companies in a particular business activity (e.g., paper making) and possibly in related activity types (e.g., production of building timber). However, the chairs of boards and the presidencies of companies rarely go unfilled for very long. We assume there is some kind of competitive market for top executives and that there are fewer top level opportunities than competent potential incumbents, but we are in no position to assess the true market for senior managerial types nor the depth of the pool

of eligibles. The logic of our approach to a test of the functional theory dictates that we look at companies that are homogeneous with respect to business activity in order to control for differentials in the scarcity of rewards and of qualified personnel. Hence, all comparisons are within, and not between business activity types. We also require variation within types with respect to size, since magnitude of responsibility is a principal indicator of relative functional importance.

The initial sample was taken from directories of large U.S. companies published annually in *Forbes* magazine.¹ The listed companies are reported with a number of indices that can be used to measure performance, responsibility and executive compensation. Companies are included in the *Forbes* directories if they rank among the top 500 U.S. companies on at least one of the following: assets, sales, total market value of common stock or net profits. The 859 companies included in the 1975 *Forbes* lists (containing 1974 data) constitute the main data source for the present study. Thirty-seven companies had too much missing data to be included in our sample. The number of companies available for analysis varies because data are incomplete for some cases. Homogeneity within business activity types was determined by classifying companies according to their principal activities as listed in the *Forbes* (1975) industry groups and as described in *Standard and Poor's Stock Guide* (1975).

Responsibility measures. The major responsibility for a company and its success or failure is assumed to rest with the top

management of a firm. Clearly, they are responsible to a variety of clients. They are obliged to protect the interests of creditors and shareholders, to maximize profit and growth. They also have obligations to the company's employees: to reward them for work competently performed, to provide them with a safe working environment and, in this day and age, to make working conditions decent and comfortable and to ensure a degree of job security, if not job satisfaction. In the present period of industrial organization, top management is not likely to escape these responsibilities to employees if it hopes to retain workers and maintain their productivity. The difficult task is to balance profitability against employee interests—to give what management must in hope of maximizing productivity and minimizing worker turnover, but to give no more than it must, lest the company become noncompetitive or unprofitable. This balancing act is reflected in the quality and price of the product or service provided for the third constituency, the consumer. Top management is obliged to see that the consumer gets, or thinks she or he gets, value for money. But the consumer must not get too much value for money if the company is to be competitive, if loans are to be secure, stockholders satisfied and employees safe and secure in their jobs and decently paid. The obvious functional requisite, probably the only obvious one, perhaps the only one, is that top management must enable the company to survive. *Pace, Davis and Moore!*

Two measures of the responsibility of top management are available from the *Forbes* directories: assets and number of employees. Stockholders' equity is another responsibility measure. Although it is not reported by *Forbes*, *Fortune* magazine publishes annual directories of selected companies which include stockholders' equity, allowing us to supplement the *Forbes* data for 607 companies (see Table 1).

These three measures are highly interrelated, particularly within activity types. In order to reduce ambiguity about the responsibility measure, only those types in which the intercorrelations among all three

¹ Although the *Forbes* directories have been published in various forms for nearly three decades, compensation data for chief executive officers are available only for the years since 1970. The time-series is further complicated, if not restricted, by a large amount of missing data for 1970 and 1971, possibly because of teething problems in developing procedures for compiling the compensation data. Once the series is sufficiently long to make a time-series analysis tempting, researchers will have to contend with the fact that companies in the lower ranks on the *Forbes* selection criteria tend to be unstable participants in the listings.

Table 1. Four Responsibility Measures by Business Activity Type

Business Activity Type	1974 Assets (\$'000,000)	1974 Stockholders' Equity (\$'000,000)	1974 Number of Employees ('00)	1970-74 Average Annual Percent Change in Assets

other two measures, it was selected to index responsibility, our operational measure of functional importance, i.e., the dependence criterion. Nevertheless, our procedure assures comparability on all three dimensions of responsibility.

Forbes data are relatively complete for 591 companies from 1970 through 1974. The data first were restated in constant 1970 dollars to control for inflation. Next, 1974 assets were correlated separately with each year 1970–1973 and with the five-year averages. All correlations were .98 or higher. Since assets are stable over the short run and since many of the smaller companies moved in and out of the *Forbes* lists over the years, use of the 1974 assets figures allows more companies to be retained for analysis than would a composite index and with no loss in rigor.

If, as we propose, assets are used to index the magnitude of responsibility, change in company assets implies a corresponding change in the responsibility carried by executives. Such changes in the magnitude of responsibility within a company are indicated by the average annual percent change in assets (in constant dollars) over the period, 1970–1974. It is clear from Table 2 (column 4) that this measure is independent of the three cross-sectional measures of responsibility.

One could also argue that changes in the assets of a company can be attributed to the success or failure of executive performance. On this line of reasoning, the measure should be interpreted as a performance rather than a responsibility indicator. No matter which interpretation is accepted, a positive correlation between this indicator and rewards is predicted by the functional theory.

Although Davis and Moore (1945) speak of prestige as a reward, when attention is focused on positions of very high responsibility, prestige defies measurement. How would one differentially rank the chief executives of IBM, Xerox and Kodak? One could consider measuring reward by semi-imponderables such as the perquisites that come with a key to the executive suite, but this would require more information about the life styles of

individual executives and the inner workings of individual organizations than may be knowable. In order to devise a test that will not bog down in debate over different rating schemes, we opt for tangible economic rewards which are confidently measurable. We accept that there is a great diversity of intangible rewards attached to any high status position, but none substitutes for money.

Three measures of remuneration are available from the *Forbes* directories:

- (1) total compensation of the chief executive officer (in \$000), including salary, bonus, deferred compensation and director's fees, but excluding stock options;
- (2) salary and bonuses (in \$000) of the chief executive officer;
- (3) average remuneration (in \$000) of all officers and directors.

Superannuation benefits and gains from exercising stock options are deferred rather than direct and immediate measures of reward. Although such information appears in annual calls for stockholder meetings as required by U.S. law, the information is not reported in *Forbes'* extensive record of U.S. companies. The facts can be secured on a case-by-case basis from company proxies and reports, and we have experimented with collating and interpreting such data from a subset of companies. For the purpose of this paper, however, we decided that the yield in improved evidence did not justify a considerable investment in data acquisition and collation time.

We do not present the detailed base data on reward as we did for the responsibility measures. However, Table 3 shows that the three reward measures are highly intercorrelated, and this fact allows us to simplify and clarify comparisons by restricting attention to the one position of ultimate responsibility, the chief executive officer.

Although total compensation (the reward measure) is not as robust a statistic as assets (the responsibility index), the 1974 reward figures intercorrelate well enough with each year separately and with the five-year average to permit use of the

Table 3. Average Within-Type Intercorrelations among Four Indicators of Executive Compensation*

		(1)	(2)	(3)	(4)
1974 Total Compensation of Chief Executive Officer	(1)	1.00	.92	.76	.33

1974 total compensation measure. This enables us to preserve the maximum number of companies in the sample. Change in compensation, indexed by the five-year average annual percent change in total compensation in constant dollars, does not correlate highly with the other reward measures. Hence, change in compensation is retained in the analysis.

Performance measures. Although our restatement of the theory does not require us to deal with societal survival, our data enable us to offer a clarifying comment on the issue. We arbitrarily identify four kinds of enterprises of relatively high societal value and four of less, or possibly negative, value. The assets of the two largest companies in each business and the executive compensation for those companies are reported in Table 4. Obviously, the findings are the reverse of the societal value postulate of the functional theory. Even though the "more essential" companies tend to be larger (twice as large on average) than "less essential" companies, their chief executives get less pay (\$58,000 less on average).

One brief word about a type of corporate service more or less essential to societal survival may be worth a thousand pictures.

Wells, Rich boasts blue chip clients and outstanding creativity. (It dreamed up the famous Alka Seltzer TV commercial—"I can't believe I ate the whole thing.") When the company went public in 1968, it had little trouble in attracting investors. The first issue of common stock sold out at

17½, and a second, in 1971, brought 21¾. This infusion of capital meant \$12.5 million for insiders (that is, people in or close to management) and \$696,000 for the corporation.

Founder and head of Wells, Rich is Mary Wells Lawrence, one of the brightest stars ever to sparkle in the advertising world. From the two public stock offerings, she received over \$3.5 million. In addition, she boasts a contract (signed in 1969 and modified in 1971), guaranteeing her a yearly salary of \$223,000 to 1981, deferred annual compensation of \$30,000 and an annual consulting fee of \$125,000 for a dozen years after her retirement. She also received "executive compensation awards" of \$185,505 in 1973 and \$168,248 in 1974. After the agency obtained what it wanted from public status—increased executive compensation, via stock options and higher salaries, and acquisition of another ad firm via an exchange of stock—Wells, Rich and Wall Street cooled toward each other. The shares faded to a skimpy 5½ in 1974. (Scheibla, 1975:9)

No further comment is needed. The reward to the creator of Alka Seltzer advertisements and the evidence in Table 4 speak clearly enough about societal survival and the immodest formulation of the functional theory.

Aside from bankruptcy as a negative indicator of company survival, *Forbes* publishes a variety of indices covering diverse dimensions of company performance. The incestuous relationship among many is obvious, and most are moderately intercorrelated in any given year and within the short time-series available. We make no

judgment as to which are more important to company survival or which combination of variables indicates whether one company is performing better than another. Six indicators are generally recognized to measure two important aspects of company performance. The first five indicators are described in *Forbes* (January 1, 1975: 38). We constructed the last indicator to minimize the missing data problem.

1. *Economic growth* is measured by:

(a) the 1970-1974 average annual percent change in sales, where the average sales for the years 1970-1974 are expressed as a percentage change from the period 1965-1970 in terms of a five-year annual compounded rate of growth;

(b) the 1970-1974 average annual percent change in earnings per share, where the average earnings per share for the

years 1970-1974 are expressed as a percentage change from the period 1965-1970 in terms of a five-year annual compounded rate of growth.

The weighted average of the intercorrelations for the sixteen activity types is only .43 (total companies=494, standard deviation=.24). Hence, both measures of economic growth are included in the analysis.

2. *Profitability* is measured by:

(a) the 1970-1974 average percent return on stockholders' equity, where the return is based on earnings per common share as a percent of the stockholders' equity per common share at the beginning of a given year;

(b) the 1970-1974 average percent return on total capital, where the return is based on net income after taxes and write-offs, but before the deduction of interest

on debts as a percentage of stockholders' equity plus the long term capital from other sources;

(c) the 1974 net profit margin which is the proportion of net income available for either stockholders' dividends or reinvestment in the company;

(d) the 1974 ratio of net profits to assets which, similar to the five-year average return on total capital, indicates the return on investment from all sources.

The 1970-1974 average return on total capital is sufficiently correlated with the 1970-1974 average return on stockholders' equity to be deleted from the analysis (Table 5). The intercorrelations among the other three measures of profitability are sufficiently modest to require their retention in the analysis.

In this paper, we do not deal with price performance on the stock market. Folklore suggests that stock price fluctuations are susceptible to factors more remote from the immediate control of management than are other indicators of company performance. Managers can strive to effect growth, cut costs, increase production and sales, and otherwise attempt to maximize profits and their actions may influence the market price of the stock. They may also try to manipulate but they cannot control the behavior of investors who ultimately determine the market price of shares. For the time being, we bow to folklore and have eliminated market price changes as a measure of company performance.

A Modest Test of an Immodest Theory

We have already mentioned that we doubt a shortage of potential incumbents exists for positions in mature, industrialized societies. There may be periods of lag in supply while educational institutions catch up with unanticipated demands or some efforts may be made to restrict supply (Tumin, 1953:389), but a shortage of positions seems to be more nearly the rule. In any case, the distributions of qualified personnel and positions within a given business activity type can be taken as constant over the short run of five years covered by our data set by restricting comparisons to within-type data. Holding constant the distribution of qualified personnel, only the key concepts of (a) functional importance, (b) reward and (c) performance need be operationalized and only two basic hypotheses need be subject to test.

Hypothesis 1. Total compensation of chief executive officers is positively related to company assets.

Compensation is positively related to company assets, and the *precondition* for a functional explanation is upheld (see column 2 of Table 6). In the most favorable case, petroleum products, 64 percent of variability (r^2) in total compensation is accounted for by assets. On average, however, only 29 percent of variability is accounted for by assets. Clearly, factors other

Standard deviations for the weighted correlations and total number of cases (in parentheses) for which complete data are available are given below the main diagonal.

than size of company must influence the compensation of chief executive officers. In addition, changes in compensation and the responsibility index (column 3 of Table 6) are moderately related in only three business activity types: supermarket chains, forest products and the miscellaneous metals and mining producers. We conclude that there is moderate support for Hypothesis 1.

Hypothesis 2. Company performance is positively related to the total compensation of chief executive officers.

No matter what measure of company performance is selected, there is no support for Hypothesis 2. Detailed findings are not presented, but Table 7 summarizes the distribution of correlations between executive compensation and performance. A more complex statistical model than the linear assumption underlying this analysis might improve the fit between compensation and performance. However, it is unlikely that any strategy would reverse a

sufficient number of the negative correlation coefficients (54 percent) to alter the conclusion that this test of Hypothesis 2 fails to support the functional theory.

Conclusion

If we accept that organizations providing a product or service which commands a price have positions that are the loci of responsibility, then if the company is to perform its functions (that is, to do its work and survive), the responsibility inherent in such positions must be competently discharged. Rewards should be related to such competent performance so that the company can retain the service of the competent performer. It can also be argued that the managers of a large company have more responsibility and more people depending upon them than those who manage a small company in the same activity. A larger company has more employees, more stockholder equity, that is, more money at stake and probably more stockholders, and more assets to manage.

Table 6. Product-Moment Correlations between Responsibility and Reward Indicators by Business Activity Type

Business Activity Type	Total Compensation of Chief Executive by Assets (1974) ^a		Change in Executive Compensation by Change in Assets (1970-74) ^b

1974 Net Profit Return on Assets	717	-.05	.24	-.13	.23

* Average annual percent change in total compensation of chief executive officer.

Managerial actions in such a company affect more people, involve more investment decisions, more capital, more consumers and more suppliers. If such a company prospers or crashes, the stakes are higher and the reverberations are greater than is the case with a smaller firm with a smaller share of the market. A testable statement of the theory suggests that such managers should be rewarded in a manner bearing some relationship to the magnitude of their tasks, and that they should perform accordingly.

We find that, on the average, executives of large companies receive more pay than executives of small ones, but there is no evidence that large companies perform better, no matter how performance is measured. Thus, there is little or no support for a functional explanation.

Alternatively, it may be argued that market forces strongly condition performance. However, our comparisons are made within business activity types over a constant time period, and external influences, including market forces, should be similar for all companies of a type. If market conditions make a difference, they are external to the control of incumbents in important positions and do not enter into the functional theory.

How are differential rewards to be explained? A plausible answer is that large

companies can provide the highest compensation with the least visible impact on their balance sheets—and do so irrespective of their performance. The mechanism for this reward pattern is simple indeed: chief executive officers influence, when they do not determine, their own compensation (cf. Simpson, 1956: esp. 133-4).

A few years ago, ITT's Harold Geneen speculated to *Forbes* that in terms of the wealth he was creating for stockholders, he might be worth \$5 million a year instead of just short of \$800,000. When we asked him this year why he hadn't raised his salary, he replied: "No one moved up there, and I didn't dare to do it alone. I still feel underpaid."

In a way, the whole system makes no sense. . . . George Scharffenberger at ailing City Investing had himself paid \$440,000, Meshulam Riklis at fouled-up Rapid-American, \$425,000. But the bosses at highly successful S. S. Kresge and Bank-America got only \$265,000 and \$249,000, respectively. (*Forbes*, May 15, 1975:234)

COMMENTS

A CRITICAL CELEBRATION OF GUSFIELD'S "THE LITERARY RHETORIC OF SCIENCE" *

(COMMENT ON GUSFIELD, ASR
FEBRUARY, 1976)

Gusfield (1976) wants to challenge the accepted view that scientific language is a neutral transmitter of knowledge. To do this, he constructs a metaphorical equation between literary and scientific discourse which allows him to use techniques of literary criticism on specimens of scientific prose. As a result of his analysis of one paper central to policy formation with respect to drinking drivers, he suggests that there is a fundamental "tenuousness or ambiguity of conclusions" (Gusfield, 1976:32) in some scientific writing.

This is an excellent pioneering essay. However, if we are to use such an approach to understanding aspects of the production of scientific knowledge (and I believe we should), it is crucial that we have the issues it raises clear at the start. Four of these issues lack clarity in Gusfield's paper:

1. What is the meaning of "knowledge" in this approach?
 2. Through what process is this scientific knowledge developed?
 3. Is Burke's critical framework the only technique of rhetorical analysis or are there alternatives?
 4. What is the relationship between rhetoric and morality in the process of knowledge construction and policy formation?
1. What is the meaning of "knowledge" in this approach?

"Rhetoric" is more than literary style. Gusfield (1976) recognizes this in quoting Aristotle's definition of this concept which directs our attention to "persuasion" as the essential element. To deal with the question of knowledge in this case, therefore, is to grasp how

* George Zollschan suggested this comment. Bart Stoodley provided a most helpful critique of an earlier draft. I remain responsible for its genesis and errors.

knowledge is related to persuasive discourse through an understanding of rhetoric as addressed speech.

The conclusion of a logical argument, if one accepts its premises, is self-evidently true irrespective of any audience's response to it. The conclusion of a rhetorical argument, on the other hand, cannot be treated as knowledge as it stands: its cognitive status has to be assessed in relation to the response of the intended audience. To maintain that scientific discourse is rhetorical, or more warily to treat it as if rhetorical (Gusfield, 1976: 17), is to formulate *scientific knowledge as the changing judgments of scientific audiences on the meaning of statements directed to them, where these judgments are understood to emerge through a process of persuasive argumentation.*

Although immanent in Gusfield's essay, this formulation is never presented in the explicit terms that clarity demands. This omission, in combination with his focus on written presentations and the rather "forced" conclusion might encourage readers to think that rhetoric in scientific presentations is but one more obstacle to scientific lucidity and, ultimately, logic. While the position of logical arguments is moot from a rhetorical viewpoint, such a conclusion would be alien to the interests that Gusfield (1976) pursued in his paper. The treatment of scientific knowledge as an emergent from a process of persuasive argumentation leads us far from the conventions of the positivisms.

2. Through what process is this scientific knowledge developed?

As far as one can tell from Gusfield's (1976) essay, he believes that scientific knowledge is found in written "scientific presentation," i.e., in the written presentation of "the theory, generalization or conclusion to which the work of the scientist has led" (p. 18). This will hardly do. The written presentation is only one stage in the construction of scientific knowledge. If we are to explore seriously a rhetorical analysis of scientific knowledge, it is critical to broaden Gusfield's presentation.

From a general rhetorical framework that

conceives speaker, argument, situation and audience as the essential aspects of persuasion, one may construct four analytic stages that are important to such an enterprise. (a) There has to be a creation of persons who are licensed to speak before a scientific audience and who can do so effectively and convincingly. (b) Such individuals need pertinent experience on which to base their discourse; they need "research." (c) This experience is reconstructed in some written presentation that seeks to make a particular conclusion plausible. (d) Finally, an authoritative audience responds to the written presentation indicating what status it has as knowledge.

(a) Without going into the whole question of the recruitment, training and certifying of scientists (restricting ourselves to written presentations), the context of the presentation (in books or journals), the author's credentials, academic affiliation and display of research support may all be taken as a presumptive guarantee (based on the gatekeeping activity of graduate faculties, peer review committees and editorial referees) of the writer's intention to speak scientifically and, hence, intention to speak scientifically and, hence, initially demarcate such presentations from nonscientific speech. Writers are tentatively licensed to speak scientifically, therefore, by a display of a variety of credentials in a rhetorical situation wherein a scientific audience expects to encounter scientific discourse. A view such as this needs to be added to Gusfield's (1976:20) useful but incomplete formulation of credentials as identifying authors by establishing their role.

(b) The second stage in the production of scientific knowledge is the most difficult to place in a rhetorical understanding of that process. After all, the research experience is only available in the reconstructions of the written scientific presentation. But can what researchers do be inferred from what they say they do, as Gusfield seems to think? Probably not. However, given our undeveloped grasp of this transformation, it must suffice here to point out the central element in this stage from a rhetorical stance. Scientists are not omnivorous in their hunger after experience; they limit their intellectual appetites to those kinds of experience which they believe can be presented plausibly in written form to a scientific audience. Some sociologists, for example, only seek out measurable experiences since they believe it difficult to speak persuasively about the unquantified to their intended audience.

(c) Rather than repeat myself, I shall deal with this third stage in the production of scientific knowledge later when considering alternatives to Kenneth Burke in the study of scientific argumentation.

(d) From the addressed character of rhetorical speech and the idea of "persuasion," it is obvious that to understand the emergence of scientific knowledge one must examine the kinds of responses *and* the kinds of audiences that give them in relation to presumptively scientific written presentations. Who responds and where? Are there few audiences or many? Of whom are audiences composed? Do these presentations and their conclusions become incorporated as "facts" in another scientist's presentation? Does that make the earlier work "knowledge"? Does the presentation become a matter of controversy, is it debated at length, or is it ignored? Over what length of time are such responses made and is the latest comment the "state of knowledge" of a particular presentation? One could continue. It is only if these kinds of questions are confronted that a rhetorical analysis can present the effect of audiences in the emergence of scientific knowledge.

3. *Is Burke's critical framework the only technique of rhetorical analysis or are there alternatives?*

There are other ways of dealing with the question of rhetorical argument in scientific discourse. It is definitely not the ambiguous genius of Burke's "pentad" or nothing. Rhetoricians have been no more willing than Gusfield (or myself) to take on the natural sciences; nor, with very significant exceptions, have they leapt to analyze discourse in the social sciences. Yet, given Gusfield's (1976) attention to sociological speech, it is crucial to mention the work of Perelman (especially 1969) wherein the sole modern treatise on argumentation that is intended to comprehend the discourse of social science is presented.

Although Perelman's sampling of proofs in the social sciences is hardly systematic, he does address himself to "the use of reason [non-logical argument] in directing our own actions in influencing those of others" (Perelman, 1969:3). It is this precise issue, cast in terms of "policy implications," that concerns the conclusion of Gusfield's (1976) essay. Valuable as are the Burkean and more diffuse perspectives employed in the paper, Gusfield has to go well beyond them to draw conclusions for scientific practise or policy formulation. To give a rhetorical approach a fair

chance of establishing itself as a viable analytic perspective (on sociological, if not all scientific discourse), it is important to begin this kind of analysis with a variety of rhetorical orientations. The systematic reflections of Perelman (1969) would be an essential addition here and might allow for the security of a reliable, empirical investigation of sociological discourse (inter-observer agreement on the interpretation of the rhetorical form of discourse) that is so difficult when using Burke's framework.

This is no place to outline Perelman's work, but it might give readers some sense of how analyses using his approach could proceed if I discuss the form of argument in Gusfield's (1976) essay from a perspective that is informed by a close reading of Perelman (1969). Briefly, I would want to ask and answer two questions. First, what is the general conclusion of the essay? Second, what rhetorical techniques are used to make that conclusion persuasive for his intended audience?

The best candidate for a general conclusion appears at the very end (as one often finds) and is contained in two short sentences:

What is at stake, however, is the necessity of the interpretation and the close connection between that interpretation and its form of presentation, its artistic element. It is in underlining the tenuousness and ambiguity of conclusions that I cannot blink at having called into question the certainty and stability of scientific interpretation. (Gusfield, 1976:32)

Readers will note the crucial switch in level of generality that occurs between these sentences. The first deals with Waller's (1967) essay, the second with all science. I submit that it is this second sentence which carries Gusfield's *general* conclusion. This leads me to my second question. What techniques are used to persuade us that this conclusion is plausible?

If I may skip a great deal of detailed analysis, it is reasonably clear (in part because Gusfield is highly moral in making his own rhetoric so transparent) that the Waller (1967) essay is used as an *example* through which is established a general rule that applies to all scientific discourse. It is through such an argument that one may establish a generalization from a particular case using rhetorical techniques (Perelman, 1969:350-62). Instances of this form of persuasion abound in sociological discourse; all samples are examples! What makes our belief in this generalization more credible is related to the character of the example and the techniques used to convey the plausibility of the conclusion *vis*

à vis that example. One approach to understanding how this is achieved would be to take Gusfield's orientation and apply it reflexively to his own essay. Another would involve some effort to adapt Perelman's general approach to the rhetorical analysis of sociological discourse (for example, Overington, 1975). Unfortunately, this is not the place for such an extended discussion.

4. *What is the relationship between rhetoric and morality in the process of knowledge construction and policy formation?*

So we turn to the final unclarity of Gusfield's (1976) essay. The difficulty here is well summarized in Perelman's (1969:59) note that "rhetorical proof is never compelling." If such proof is not compelling, how shall we decide on the status of conclusions in scientific or, more narrowly, sociological discourse? Gusfield clearly recognizes this problem in his observation on the "unnecessary" character of scientific interpretations (p. 32); but he skirts the issue.

His avoidance may well be rooted in the "Prologue" to the (1976) essay, where (however ironically) he calls rhetoric "the skill perfected by the Sophists" (p. 16). Indeed, Plato (1952: 11) asserts that the "sum and substance" of the Sophists' skill is that of "persuasion." But Sophists care only for persuasions that succeed. Is this how we must think about sociological argument? And if violence is the ultimate persuader, is power the basis of knowledge? Surely we must ask whether we will accept that the *techniques* of persuasion are the "sum and substance" of rhetoric (and thus the grounds of conviction in scientific argument), or whether we will persist with Plato (1952:106) in the view that "rhetoric, like every other practice, is always to be used to serve the ends of justice, and for that alone," even if we might want to substitute "truth" for "justice" in most cases?

The acceptance of a rhetorical approach to scientific (particularly sociological) speaking forces us to face fundamental difficulties in our practice. How are we to formulate truth and justice as ends for persuasive discourse? How does a conventional agreement produce True knowledge? If the "truth" of our knowledge is based on social conventions, what are they? Would it help us to see many of the more important debates in sociology as a struggle over such conventions? Can we really avoid an investigation of how social power operates in the process of knowledge construction? The questions mount.

The pioneering excellence of Gusfield's (1976) paper can only be assisted by a confrontation with the issues raised in this attempt to clarify the radical importance of a rhetorical approach to scientific knowledge.

REPLY TO OVERINGTON

Since publishing the paper on literary rhetoric of science (Gusfield, 1976), I have had a good deal of correspondence from which I have profited both in understanding and in progress on my current book on knowledge and policy. Michael Overington's (1976) comments raise a number of questions. Some of these had not occurred to me, and some I have been meditating on for many years and expect to mediate on for several more. I am grateful to him as well as to others for these questions.

The most difficult is the problem of the meaning of knowledge in my article. I wish I had a good answer, not only one that would satisfy readers but would satisfy myself as well. I think there are two different problems: one is how is it that scientific findings take on significance or meaning? This involves the interpretation of data rather than the second question: the validity of those findings themselves. I view my own paper as oriented chiefly to the first of these questions because it is here that science moves toward action. This involves understanding how it is that

data become translated or transferred into conclusions and generalizations. My intention in the published paper was to raise the possibility that the use of literary techniques of analysis might help us in understanding how it is that data are developed and conclusions are derived. I recognized (indeed, the revisions on the original paper were a small effort in that direction) that the published paper raised and dodged as many questions as it attempted to solve. Had I waited to have all of these answered in my own mind, I doubt if the paper would ever have been finished. It is an effort to open up a mode of analysis that I hope the paper may be of worth.

As to how scientific knowledge itself is developed, I think Overington has put his finger on an important problem. My paper is by no means a substitute for a more thorough analysis of the relationships between audiences and scientists. It is an effort to try to understand the nature of presentation in science as against that of other modes of communication such as poetry or journalism. I certainly erred, and quite consciously as a rhetorical device, in referring to "the literary rhetoric of science." Since then I have made the acquaintance of Bruno Latour who is conducting field empirical studies of biological scientists. Like myself, he has found the study of these as rhetoric of considerable value. He suggests, however, that it may indeed be the case that social scientists and even medical researchers feel a stronger necessity to articulate a conception of "scientific method" than do workers in many other scientific fields whose credentials are more readily taken for granted. I certainly did not mean to suggest that Burke, Frye and Booth represent the best and only mode of literary criticism of science. I used the three because I knew of them. (Overington has led me to read Perelman.) I am not a literary critic and have not studied literary criticism in any formal fashion. Indeed, I have sent this paper to several colleagues in philosophy and literature and have been met by the stoniest of silence. It suggests to me that they view it as very old hat literary criticism and, consequently, not to be noticed. It may indeed be that; I don't know. But intellectual currents sometimes run even stronger than the river, and it is not terribly crucial for what I hope to do in the paper that I use this or that particular literary critic. Again, my aim in this paper was to say, let's see where we can get by examining scientific documents as if they were artistic ones. I have come to learn that both by my own temperament and

possibly by the sure difficulty of the problem, I need to be something of a "know nothing" who proceeds without being definitive about my philosophical and, sometimes, even theoretical assumption.

It is evident that I have written this letter in a style of "fake humility" about my ideas and my paper. Yet, as one examines the development of areas known as "the state of the art," they generally proceed as if each piece were a definite and finished product. In that sense, they can be contrasted with the also evident way in which one paper is a part of a dialogue and can be seen less as a definitive statement and more as the first round in a set of exchanges. This is what Latour seems to be finding, and it makes the necessary exchanges less matters of cross-examinations and defense than part of the essential character of the scientific community.

SOCIOECONOMIC STATUS AND CRIMINAL SENTENCES: IS THERE AN ASSOCIATION?

(COMMENT ON CHIRICOS AND WALDO, ASR DECEMBER, 1975)

Chiricos and Waldo (1975) do well to remind us that the empirical evidence for the existence of a strong association between the socioeconomic status of defendants and the severity of the criminal sentences they receive is weak. Their own analysis of prison sentence lengths in Florida, North Carolina and South Carolina finds no evidence for such an association. In assessing the evidence presented on this question and its bearing on the conflict perspective, several points must be kept in mind:

(1) A finding that defendants of different SES receive sentences of equal length is only inconsistent with the claim that lower SES defendants receive more severe sanctions for the same behavior if the offenses committed

are of equal gravity. This may not have been the case, because there could have been class differences in rates of pretrial detention, in resources available to charge and plea bargaining (which in some jurisdictions involves the judge directly), in the presence of mitigating or aggravating circumstances, and in outright differential treatment on the basis of class at all earlier phases of case processing. Evidence for such differences has been reported in previous studies (see, for example, Nagel, 1969:81-112). If lower SES defendants were less culpable than their middle and upper SES counterparts, then the equal sentences they received would constitute evidence of *unequal* treatment. Moreover, the propositions Chiricos and Waldo cite as predicting unequal treatment concern all the dispositions meted out. Yet, as Chiricos and Waldo concede, their study was confined to prison sentences. As many of the dispositions for some of the offenses they studied presumably did not involve incarceration at all (e.g., probation), their study has not excluded class differences in the choice of sanction type.

(2) Some extralegal variables found to be important in other studies were not included in this analysis. One of particular interest is the status of the victim. From a conflict perspective, one might anticipate that middle- and upper-class decision makers would experience little alarm or threat from crimes in which the poor victimize the poor. If judges are drawn from middle and upper strata of the population, one might expect them to feel most threatened and to respond with more severe sentences when victims are most like themselves. Much of the evidence that exists on this point has concerned race rather than class. Wilson (1973:161-4) suggests that in some communities police do not take black complainants very seriously. Earlier studies of sentencing (Garfinkel, 1949; Green, 1964) report inconsistent findings as to the effect of victim's race on sentence; however, a recent study of death sentences for rape in Georgia (Wolfgang and Riedel, 1975) reports a very strong interaction effect involving the race of victim and race of offender. In a stepwise multiple discriminant function analysis, the interaction between race of victim and race of offender entered first and was highly significant in separating death penalty from non-death penalty decisions, while the race of victim alone and the race of defendant alone were not statistically significant. As far as class is concerned, a recent study of homicide sentences in a large northeastern U.S. city

found that when information about class of victim and defendant was included in a path analysis for sentence outcomes, sentences were higher when the victim was of higher SES and lower when the offender was of higher SES (Swigert, 1975). Failure to consider such effects could lead to a misleading conclusion that class was unimportant in sentencing.

In light of these deficiencies, it is fair to say that the data provide no support for the existence of class differences in sentence severity, but are also not incompatible with some patterns of class differences in sentencing.

(3) Chiricos and Waldo analyzed dispositions for the years 1969-1973. During the preceding decade, a number of events took place which may have tended to reduce class disparities in sentencing. One of these is the growth of black political power, manifested in such forms as increased black representation on jury rolls, on prosecutorial and public defender staffs, and on the bench, as well as increased voting strength. The impact of these changes is suggested by James Gibson's study of sentencing in Atlanta (cited by Nagel and Neef, 1976) in which it was found that white judges were giving black defendants harsher sentences than whites within a given offense category, while black judges were reversing this pattern. Failure to disaggregate sentences according to the race of the judge would, in such instances, mask patterns of discrimination. A recent study of the sentencing of California felony offenders (Pope, 1975) also is consistent with this suggestion. An analysis of lower court sentences in 12 California counties found substantial racial differences in disposition in rural areas when legally relevant variables were controlled, but not in urban areas. The black population is concentrated in cities, and it is there that black political strength would be greatest.

In the same period, the civil rights movement may have changed attitudes toward unequal treatment, as publicity concerning inequities in the criminal justice system also may have done. Even without changing attitudes, such publicity could lead to changes in sentencing patterns on the part of judges concerned with preserving the legitimacy of a system under attack. In a political system whose legitimating ideology places great emphasis on formal equality, one would least expect discrimination where decision making is exposed to public view, as in judicial sentencing. It would be more likely to appear at those levels where decisions have less visibility

(police, prosecutorial, parole) and in the legislative determination of the seriousness of offense categories.

In view of the association between race and class, such developments, if they did influence sentencing, would tend to reduce class differences even if they affected only black defendants. If they spilled over to help white defendants as well, the reduction would be even greater.¹ In light of these considerations, it would be of interest to see whether recent sentencing patterns represent a change from earlier periods.

In any event, from the point of view of theory, it is not by any means inherent in a conflict perspective to assume that low SES defendants will always be disadvantaged in court. The collective activities of socially disadvantaged groups can generate sufficient power to offset traditional disabilities. To contain conflicts in a socially unequal society, the upper class may at times need to operate according to universalistic criteria, especially in the most visible spheres of public life. When a class rules, it does not necessarily do so free from all constraints.

IS THERE A CLASS BIAS IN CRIMINAL SENTENCING?

(COMMENT ON CHIRICOS AND WALDO, ASR DECEMBER, 1975)

Chiricos and Waldo claim to have tested one of the propositions of "conflict criminology" and found it wanting. But there are problems with their procedure, and I shall argue here that an alternative method of analysis is more appropriate.

The proposition in question, asserted in the first place by Chambliss (1969:86), is that "the lower class person . . . if found guilty, [is] more likely to receive harsh punishment than his middle or upper class counterpart." To test this, Chiricos and Waldo assemble data on a cohort of criminals sentenced to prison for varying periods. They compute a socioeconomic status score for each inmate and, treating SES as a continuous variable, correlate it with length of sentence. They conclude that generally there is no significant relationship between a defendant's SES and the length of his sentence.

The problem with this procedure arises from the investigators' decision to treat SES as a continuous variable. This may be, in part, a result of imprecision in the writings of conflict criminologists themselves; they do sometimes formulate their propositions in continuous terms. However, the proposition in question treats status as essentially dichotomous: it compares the "lower class person" with his "middle or upper class counterpart."

Moreover, there are good theoretical reasons for treating status as a dichotomy rather than as a continuous variable in this context. Studies have shown (see Warner, 1969:182)

that although people may be sensitive to quite minor status distinctions between themselves and others they are largely insensitive to minor differences among people whose status is very different from their own. Middle or upper class judges thus are unlikely to make fine status distinctions among the predominantly lower class defendants whom they sentence. They are unlikely, for example, to perceive any status difference between two unemployed men, one with eight years schooling and the other, seven. It seems more plausible to suggest that judges will make status discriminations as follows. *Either* the judge perceives the defendant as someone with whom he can identify, someone with a similar background to his own who is not inherently criminal and whose criminal behaviour is felt to be an unfortunate consequence of particular circumstances or social pressures, *or* he sees the defendant as belonging to a lower social class and, as such, prone to criminal behaviour. If judges, in fact, think this way, then an adequate test of the Chambliss proposition must treat status as a dichotomous variable.

Furthermore, one of the reasons that conflict theorists give for expecting more lenient treatment for high status defendants is that status is often an indicator of political power and that, perhaps inadvertently, the courts tend to deal more warily with the politically powerful in order to avoid adverse reaction (Chambliss and Seidman, 1971:475). But the great majority of defendants are quite powerless politically, and it is only the few middle and upper class defendants who might be expected to wield some degree of power. The theory thus requires a comparison between those who have some degree of power and those who have none—between, in other words, the lower class on the one hand and the middle and upper classes on the other.

The above arguments imply that there will be no significant relationship between SES score and length of sentence *within the lower class*. Yet because middle and upper class inmates constitute a tiny fraction of the cohort studied (as of course they will in any such research) it is effectively this "within-class" relationship which Chiricos and Waldo are measuring and which, not surprisingly, they find to be insignificant. A more appropriate test of the Chambliss proposition would be to separate upper and middle class inmates from lower class inmates and compare the average length of sentence for individuals in these two groups. Of course, the choice of just where to dichotomize the SES continuum

would be arbitrary to a degree, but it would need to be made in such a way that the great bulk of defendants fell within the lower class.

Broadening this discussion beyond the task which Chiricos and Waldo set themselves, I suspect that whatever method of analysis is used, the class bias involved in sentencing individuals who have committed the same type of crime will be found to be relatively slight. The real class bias in sentencing lies elsewhere. The key to it is that, as Chiricos and Waldo demonstrate, there are so few middle or upper class people convicted of or, for that matter, charged with the traditional crimes of murder, robbery, larceny and so on. This is simply not the way higher class people behave. The illegal activities of the middle and upper classes are typically such things as income tax evasion and, in the case of businessmen, price fixing, violation of pollution laws and misrepresentation in advertising. Moreover, the sentences for such crimes are normally very light, often amounting to no more than warnings not to offend again (injunctions). In the most celebrated case of white-collar crime in American history, a price-fixing conspiracy among 29 electrical equipment companies which is estimated to have cost the general public more money than is reported stolen by burglars in an entire year in the U.S. (President's Commission, 1968:24), the principal defendants received sentences of only 30 days. The fact is that illegal behaviour of the type typically committed by the middle and upper classes attracts light sentences while crimes typically engaged in by the lower classes attract much harsher penalties. This is the real nature of the class bias in sentencing.

ON METHODOLOGY, THEORY AND IDEOLOGY *

(COMMENT ON CHIRICOS AND WALDO, ASR DECEMBER, 1975)

Chiricos and Waldo (1975) have recently presented research which purportedly tests a conflict theory proposition and provides rather conclusive evidence that the proposition is invalid and, thus, the theory is weakened. It is contended here that their inquiry fails to test adequately the proposition and, thus, the theory. Furthermore, even if such a test had been undertaken it may be irrelevant given possible differences in the ideology and methodology of functional and conflict perspectives.

Chiricos and Waldo purport to assess empirically the worth of the following two propositions from conflict criminology.

Chambliss (1969:86) proposes that a lower class person "is if found guilty, more likely to receive harsh punishment than his middle or upper class counterpart."

Chambliss and Seidman (1971:475) propose that "when sanctions are imposed, the most severe sanctions will be imposed on persons in the lowest social class."

Chiricos and Waldo note that the latter proposition is only one (number fifteen to be exact) of twenty-three propositions; however, they assert (1975:755, fn.5) that their research "is clearly addressing one of the two or three most important propositions in Chambliss and Seidman's theory" (emphasis added).

Therefore, the empirical question posed is the extent to which social class influences the harshness of sanction received by convicted persons.

Chiricos and Waldo use data on prisoners in three states to test the above propositions. Therefore, they are not testing the propositions as stated by Chambliss, and Chambliss and Seidman. The authors note this limitation.

It must be recognized that a more complete assessment of the sentencing process would include those sentences received by probationers

* I would like to acknowledge the helpful comments and suggestions by Colin Goff, John Klein and Arthur Frank on an earlier draft of this comment.

as well as by those remanded to prison. However, these data are unavailable at this time and the present research must be regarded as but a partial test of the Chambliss-Seidman proposition. (Chiricos and Waldo, 1975:758, emphasis added)

Thus, they have moved from "clearly addressing" the proposition to a "partial test." In fact, the analysis fails to test the propositions, and the data presented could easily be interpreted as supportive of the conflict proposition rather than negating that perspective.

First, they are addressing a population which has received the most severe possible sanction, i.e., incarceration. This population is actually but a sample of a much larger convicted population receiving probation, fines, suspended sentence, restitution and/or other available sanctions (the extent to which the prison population approximates those convicted is an unknown, but crucial factor). Therefore, Chiricos and Waldo have a small and select representation of convicted persons and actually are testing their own proposition which they believe is derived from conflict theory—among prison populations those with the lowest SES status will have received longer sentences for the same offense than those with higher SES status.

This is an excellent example of the data's inapplicability to the theory because of the nature of the confined population. The Chambliss, and Chambliss and Seidman propositions specifically use social class as the significant independent variable in the imposition of sanctions—"when sanctions are imposed, the most severe sanctions will be imposed on the persons in the lowest social class" (Chambliss and Seidman, 1971:475, emphasis added).

However, Chiricos and Waldo apparently only have "lower class" people in their population! Therefore, they are attempting to make "within-class" distinctions while the conflict theorists are talking about "between-class" differences.

While Chiricos and Waldo find "within-class" differences among inmates in SES scores, the significance of their initial question is largely lost. They note that there is sufficient "class" variation to provide appropriate testing (1975:759, fn.14). However, "sufficient" variations around means of 32.89, 31.86 and 36.59 on a scale of 100 appear "insufficient" to address the initial proposition. While these within-class differences might interest the researcher, they do not begin to address the initial question posed by conflict theorists.

Since a cursory look at any state prison

population provides ready evidence of the class nature of its inmates, Chiricos and Waldo's "discovery" of the low SES nature of their population should not be surprising. In fact, such data support the propositions being tested since incarceration is the most severe sanction meted out by courts. Furthermore, according to Chambliss and Seidman's (1971) theory of legal systems in complex societies, differences in the class basis of laws, their enforcement and administration would have the "cumulative effect" of leading to disproportionate representation of the lower class in prisons.

Chiricos and Waldo (p. 758) address this problem in their discussion of computing SES.

Given the backgrounds of most persons who filter through the criminal justice process to the prison level, it makes little sense to speak of "high," "middle" and "low" status in traditional terms.

From the conflict perspective, the question might be why there is such a disproportionate representation, rather than an attempt to assess within-class differences among the incarcerated. The issue is resolved for Chiricos and Waldo when they state (1975:759, fn. 14):

Unfortunately, since this is the nature of the "real world," this is the kind of population the researcher is forced to use if sentence length is to be the dependent variable.

Unfortunately, the nature of the "real world" as defined in the initial proposition is radically changed by largely eliminating the most significant variable, i.e., social class. While one obviously cannot "create" inmates of middle and upper classes, if those convicted offenders not incarcerated had been included, it would likely increase representation by other classes. The nature of the "real world" evidenced by the skewed class distribution of inmates can be interpreted as supporting the Chambliss proposition specifically, and conflict theory in general.

Chiricos and Waldo (p. 766) conclude that:

What the foregoing data suggest, rather conclusively, is that the socioeconomic status of convicted criminal offenders is unrelated to the severity of the state's official sanction, as reflected in the length of prison terms assigned by the courts. Such a conclusion, which strongly contradicts common folklore, the general expectation of conflict criminology and the specific proposition of Chambliss and Seidman . . . , is given added credence by the fact that it is true for a total of seventeen different criminal offenses and for three separate states.

It would be more appropriate to conclude that the foregoing data suggest that "within-

class" differences in SES scores among lower class inmates is unrelated to the severity of their sentences as reflected in the length of prison terms assigned by the courts. Such a conclusion, which may surprise some, fails to address the Chambliss and Seidman proposition specifically, and conflict theorists' concerns generally.¹

A larger and potentially more significant issue is raised by Chiricos and Waldo's attempt to test a conflict theory proposition. This brings us to the relationship between ideology, methodology and theory and the possible incompatibility of testing one perspective's theory from another perspective's methodology. While the authors note that conflict theory has ideological appeal as a "world view," they fail to take seriously this relationship between ideology, "world view" and the practice of science.

Chiricos and Waldo (p. 754), however, note that "conflict criminology begins with a set of domain assumptions that are radically different from those of functional criminology." What are the methodological ramifications of these differences? Even if one were to accept their judgment that there are no paradigms in sociology, it is arguable that these "competing theories" have different methodologies.²

¹ Purposefully, I have not addressed their specific findings because the other issues overshadow them and render their interpretation largely meaningless for the initial question. Nonetheless, it is interesting to note that most inmates in Florida are black (although racial data are not presented for the other two states—North Carolina and South Carolina—I would guess they would be similar to Florida) in great proportion to their population in the state (p. 763). One interpretation of such data (there obviously could be others) from conflict theory would be that this reflected the cumulative effect of racial oppression in the making of laws, their enforcement and the administration of justice.

It is of particular interest to note that only blacks commit forcible rape in Florida as defined by the lack of any whites incarcerated for this offense. Might this reflect the history of black-white relationships and their representation in the laws, their enforcement and administration? Of course, the above-noted data could be interpreted differently, which is the basis for the next section of this comment.

² While the thrust of this argument is not to make a case for paradigms in sociology, I would conclude that Kuhn's (1970) analysis, particularly his notion of scientific subcommunities having varying paradigms, is applicable to sociology. While the case for "normal" science in sociology is more difficult to make, it is increasingly being

While Chiricos and Waldo use Chambliss (1973) as a basis for differentiating functional and conflict theories, they fail to note that Chambliss identifies functional and conflict perspectives on the basis of their varying focus, methodologies and underlying ideologies. Using Durkheim and Marx as exemplars of the functionalist and conflict paradigms, respectively, Chambliss (1973:4) derives four fundamental issues separating them "(1) the role of history in sociological analysis, (2) centrality of a critical analysis of the existing social conditions, (3) the methodology appropriate to social sciences and (4) the meaning attached to the normative system." Chiricos and Waldo address the issues in (2) and (4), but leave (1) and (3) virtually untouched. Chambliss (1973:4) states that while both study history they do so differently.

Functionalists see society as a reality which is unconnected with a particular historical period and look for those social needs which all societies have. . . . The Marxian analysis begins with the observation that the needs, characteristics, ideologies, and institutions of a particular society are a reflection of that society's historical condition—especially the material conditions (the mode of production) at that particular historical moment.

Regarding appropriate methodology, Chambliss states the Marxian conflict perspective sees the social scientist as necessarily engaged in bringing about the changes implied by his analysis.

The ultimate test of a theory's utility is not its logical structure or its fit with empirical data but its ability to create workable recipes for changing the existing set of social conditions (both material conditions and the superstructure derived therefrom). (Chambliss, 1973:4, emphasis added)

Regarding the worth of conflict theory, Chiricos and Waldo (p. 754) state:

However persuasive the logic or appealing the scientific utility require that it be formulated as testable research hypotheses which can direct the accumulation of relevant empirical ideology of such an argument, its validity and evidence. It is on the basis of such evidence that the acceptability of a "conflict perspective" as an alternative world view in criminology specifically, and sociology more generally, will ultimately be determined. . . . (Emphasis added)

These two contrary positions on the purpose and nature of science reflect radically

asserted that sociology is a multiple paradigm science (Friedrichs, 1970; Ritzer, 1975) and that criminology also has competing paradigms (Taylor et al., 1973; Reasons, 1975). Recent discussions of conflict methodology are presented by Lehmann and Young (1974) and Young (1975).

different assumptions. Chambliss is presenting an activist theory of knowledge emphasizing the methodological differences between functional and conflict perspectives. This approach closely follows some of Horton's (1966) major distinctions between order (including functional) and conflict perspectives. In discussing the significant methodological differences between order and conflict theories, Horton identifies the order perspective with the natural science model, multiple causality and conditions of objectivity while the conflict perspective emphasizes the historical model, unicity and utility in terms of the observer's interests (objectivity discussed in the context of subjectivity). Chiricos and Waldo's analysis clearly fits the natural science model of objectivity and a passive/receptive theory of knowledge. Thus, while Chambliss rejects some of the major tenets of neo-positivists³ and emphasizes the utility of theory for social change strategies (like Horton), Chiricos and Waldo assume that the acceptance of a theory is based upon its fit with the "empirical world." This basic disagreement derives from differing perspectives on the role of ideology in the practice and development of science.

Chiricos and Waldo, like many others, tend to go about "normal science" within the confines of certain domain assumptions and directives without addressing the significance of ideology in the development of scientific theories in general and criminological ones

specifically (Radzinowicz, 1966; Miller, 1973; Quinney, 1972; Gordon, 1973; Reasons, 1975). The nature of one's "world view" and its developmental process is greatly influenced by "irrational" and "particularistic" factors as well as by "rational" and "universalistic" factors (Dolbeare and Dolbeare, 1973; Marchak, 1975). This is not to say that ideologies and world views never change among "laymen" and "scientists"; however, it entails much more than the "presentation of the facts" to make a person accept an alternative "world view." By definition, the concept of "world view" entails much more than an impassioned presentation of facts. As Kuhn (1970) notes, one filters the facts through a "world view" already established which predefines the way of doing science, including determining the worth of theories.

Thus, the differences between functional and conflict perspectives may include irreconcilable ideological, theoretical and methodological assumptions which may make it impossible for either perspective to test and judge the other within these assumptions. Therefore, the test of the conflict proposition by Chiricos and Waldo, even if "appropriately done," may not grasp the nature of the issues involved. As Kuhn (1970:146) notes:

If as I have already urged, there can be no scientifically neutral system of language or concepts, then the proposed construction of alternative tests and theories must proceed within one or another paradigm-based tradition. Thus restricted it would have no access to all possible experiences or to all possible theories. As a result, probabilistic theories disguise the verification situation as much as they illuminate it.

Charles E. Reasons
University of Calgary

³ The major characteristics of criminological positivism are that it (1) denies free will, (2) divorces science and law from morals, (3) proclaims the priority of science and believes in the existence of invariable social laws (4) emphasizes the unity of the scientific method for social and natural sciences, (5) emphasizes quantitative research, not qualitative, and (6) holds causality and determinism as paramount concerns to be pursued through observation (Mannheim, 1960). While noting that all social science is deterministic, Matza (1964) distinguishes between "hard" and "soft" determinism. The former has long been the major thrust of American criminological analysis and closely adheres to the characteristics of positivism noted above, while soft determinism allows for the incorporation of a degree of free will or choice in human behaviour. Matza (1969) later suggests that the positive school of criminology separated the study of crime from the workings and theory of the state and he advances a naturalist perspective of deviance, including crime. Of course, determinism and free will are not mutually exclusive but a matter of degree, i.e., some are more free than others (Wilkins, 1968; Pap, 1962).

REPLY TO GREENBERG, HOPKINS, AND REASONS

A problem facing any scientific perspective is what to do with contrary evidence or "bad news" such as that implied for some aspects of conflict criminology by our recent sentencing research (Chiricos and Waldo, 1975) and other related studies (Hagan, 1974; Hewitt, 1975; Willick et al., 1975). The commentaries of Greenberg, Hopkins, and Reasons reflect contrasting options for dealing with the "bad news." The first option, essentially Greenberg's and partially Hopkins', considers the findings "real" (with some limitations) and contributes to the renewed growth of conflict theory by suggesting ways in which "no relationship" between SES and sentencing could make sense—even in conflict terms. The second option, essentially Reasons', denies the reality of the "bad news" or the relevance of such news for the conflict perspective, thereby preserving the integrity of the proposition in question. Our reply will underscore the limitations and dangers of the second option, while hopefully expanding the constructive input to conflict theory of the first option.

At the most general level, Reasons argues (with support from Hopkins on this issue) that our data "fit poorly" with conflict theory and should not be regarded as "bad news" at all. Reasons further argues that *any* empirical data may be irrelevant anyway, because the conflict perspective employs unique and distinctive standards of value in judging concepts and theories. The "poor fit" and "irrelevance" arguments are briefly summarized as follows:

Poor Fit: Studies such as ours, which use available populations of defendants, necessarily have skewed distributions of social class or SES, inasmuch as most higher status persons never penetrate the criminal justice system. Thus, our data presumably forces us into a *within-class* analysis of a *between-class* issue. *Irrelevant:* Studies which rely upon traditional empirical methodologies are not especially relevant to assessing the value of conflict propositions because of the latter's ideological emphasis upon praxis or action as the determinant of an idea's value.

We contend that the "poor fit" argument hinders the development of conflict criminology because it commits its proponents to a model of social control that is ambiguous, insufficient and, quite possibly, unnecessary on both empirical and theoretical grounds. The "irrelevance" argument hinders conflict theory because it commits its proponents to a kind of false consciousness which Gouldner

(1975) shows to follow from a misunderstanding of the relationship between ideology and objectivity.

On the Poor Fit between Theory and Data

When theory and data are poorly matched, the problem may lie, of course, either with the conceptualization or the measurement of reality. We contend that the problem of fit in this instance is more likely due to inadequacies with theory than with methodology, for reasons that are briefly noted here.

First, we note that it is difficult to determine when an adequate fit exists between theory and data because of considerable ambiguity in conceptualization, not only between conflict criminologists, but within the propositions of Chambliss and Seidman's (1971) theory. The problem is most acute when trying to determine the appropriate independent variables in conflict accounts of criminal justice outcomes. While Chambliss and Seidman employ "social class" as the primary determinant, the degree of consensus among conflict criminologists on this question is minimal. For example, Quinney (1970) relies upon "conflicts" between "pluralistic interests" while Turk (1969) employs "conflicts" between "authorities and subjects in imperatively coordinated associations." Davis (1975) comes closer to social class with her use of the "relative amount of resources held by the conflicting party." Still, for Taylor et al. (1973:273) none of these (presumably they would include Davis) is really adequate, for none shows how state sanctions are "intimately bound up with the structure of the political economy of the state." In short, the conceptual apparatus by which conflict theorists explain criminal sanction is highly varied and seldom relies upon a simple specification of social class discrimination.

A closer look at Chambliss and Seidman (1971) raises further doubts about what their theory intends by the concept of "social class." That theory not only employs several *different* concepts to reference the same phenomenon (presumably poverty) but conceives of that phenomenon in *both* discrete and continuous terms. The nature of the problem is readily seen in propositions #13, #14 and #15 from Chambliss and Seidman (1971: 475):

13. Therefore, those laws which prohibit certain types of behavior popular among lower-class persons are more likely to be enforced while laws restricting the behavior of middle- or upper-class persons are not likely to be enforced.

14. Where laws are so stated that people of all classes are equally likely to violate them, the lower the social position of an offender, the greater the likelihood that sanctions will be imposed on him.
15. When sanctions are imposed, the most severe sanctions will be imposed on persons in the lowest social class. (Emphases added)

From the foregoing, it is apparent that propositions #13 and #15 deal with "social class"—though the concept is not defined—while proposition #14 deals with "social position"—also undefined. More importantly, while #13 enjoins a comparison of "lower-class" defendants with "middle-" and "upper-class" defendants, propositions #14 and #15 are stated so that differences in social position or class can be understood in continuous terms. Indeed, the only consistent point of reference in those propositions is the "lower" or "lowest" end of the continuum. Thus, we would argue that considering all three propositions, the most relevant test would compare differences in sentencing outcome between the "lowest" status defendants and all others—a comparison which data such as ours (omitting upper status persons) obviously can make for the population at risk. In short, the unavailability of upper status defendants in our sample would not appear to disqualify the data from application to the Chambliss and Seidman (1971) theory.

Though we chose—for reasons not unrelated to Chambliss and Seidman's concepts—to treat SES as a continuous variable in our initial paper, we have pursued Hopkins' suggestion to handle the matter empirically in dichotomous terms. Thus, we have compared the *lowest* status defendants—somewhat analogous to "dangerous classes" (Silver, 1967)—to all of the remaining defendants in our Florida sample.

Cutting points for determining the "lowest social class" using an SES continuum must be, as Hopkins notes, an arbitrary matter. We have approached the task from three points of view. In the first instance, we have compared the mean sentence received by the bottom 5% (< 10) on the SES distribution with all others (≥ 10) as well as the bottom 12% (≤ 15) versus all others (> 15). The latter dichotomy renders a "lowest class" which closely approximates the bottom class identified by Willick et al. (1975) and by Laumann (1966) as unskilled and semi-skilled workers. We have also followed Hopkins' suggestion—though we think it more defensible to make the foregoing dichotomies

—that "the great bulk of defendants" fall within the lowest class. Toward that end, we have compared the bottom 90% (≤ 54.3) with the top 10% and the bottom 95% (≤ 63.5) with the top 5% of our sample. Our third dichotomy split the SES distribution at the median (30.0). It should be noted that, based upon the five social class categories employed by Willick et al and by Laumann, our sample extends well into the second highest class—referred to as "upper-middle" by the former and as "semiprofessional and middle level business" by the latter. Thus, it is difficult to sustain the argument that we consider only *within-class* differences.

The data, examined dichotomously with the use of t-tests, support our initial findings. In *no instance* did we find lower status defendants receiving significantly greater sentences than higher status defendants for the same offenses. Beyond the issue of statistical significance and excluding comparisons when fewer than ten cases were available for any status and offense category, we found that lower and higher status groups were almost equally likely to receive the stronger sanction. When the lowest class comprised basically unskilled and semiskilled workers (first dichotomy), it received higher sentences in nine of the seventeen available comparisons. When the lowest class included the "great bulk of defendants" (second dichotomy), it received the stronger sanction in six of eleven comparisons; and for the median split (third dichotomy), the lowest class received higher average sentences in six of thirteen comparisons.

Pursuing the question of "poor fit" in another direction, it seems reasonable to consider whether the lack of fit is due to the application of a faulty theory to the data at hand. As articulated by Chambliss and Seidman (1971), the theory is stated in simple and sufficient terms: social class is inversely related to sanction severity. The stark simplicity, involving but *one* determinant—social class—may be insufficient to the task of describing and explaining sentencing realities, even from within a conflict perspective. Indeed, this insufficiency is clearly recognized by both Hopkins and Greenberg, with the latter observing that "... it is not by any means inherent in a conflict perspective to assume that low SES defendants will always be disadvantaged in court."

We are suggesting that if the concept of social class has a viable role in conflict explanations of sentencing, it is likely not on

the basis of a simple model of class discrimination. To insist on such a model is to ignore the bulk of empirical evidence and the contributions of more recent conflict criminologists who specify additional contingencies for a conflict explanation.

Perhaps the most significant contingency is perceived *threat* to elite interests, a circumstance whose variation need not be isomorphic with variation in social class. This issue has been explicitly recognized by Spitzer (1975), Davis (1975) and Lofland (1969), and it is implicitly present in the discussions of conflict by Turk (1969) and Quinney (1970). Though Spitzer's analysis is not specific to the question of sentencing, he does argue that social control varies with the nature of threat posed by various "problem populations" within capitalist society. "Social junk" comprises non-productive citizens who are either too old, young, feeble, infirm or insane to warrant strongly punitive control measures. "Social dynamite," however, represents surplus labor that is young, able, angry, alienated and capable of revolutionary intention, thereby justifying harsher control sanctions.

The work of Turk (1969), Lofland (1969) and Davis (1975) suggests the relevance of additional contingencies of threat, such as the size, degree of sophistication and level of organization of threatening groups. Greenberg, in his commentary, made careful note of the victim's character and relationship to offender as consequential for threat that may be perceived and responded to by the courts. In short, threat is but one of the more frequently mentioned contingencies of social control that cause us to doubt the sufficiency of social class in a conflict theory of sentencing.

One might argue further that social class isn't even necessary for a conflict explanation of sentencing, or at least that conflict theory shouldn't be surprised if social class were inconsequential. This appears to be Greenberg's point when he observes that movements of the 1960s—such as the civil rights movement—may have increased the liberal self-consciousness of bourgeois justice, or at least the fear of appearing to violate one's legitimating ideology of egalitarianism. Hopkins, as well, argues that the inconsequential character of social class for sentencing should not be surprising to a conflict theorist, inasmuch as "the real class bias in sentencing lies elsewhere"—particularly in legislative decisions which attach stronger penalties to typically lower-class activities and lighter penalties to

white-collar behavior. The two arguments are readily combined. Given the conflict assumption that law and the definition of crime are part of the superstructure whereby ruling class interests are both protected and excluded from serious criminal sanction, then an ideology and even the practice of egalitarianism at the point of sentencing should pose no threat to elite class interests. In fact, such egalitarianism effectively screens critical attention from the ways in which class control is exercised within criminal justice. Ironically, if we persist in our belief that discrimination exists in sentencing, then we reduce the general credibility of the conflict position and, at the same time, we divert critical attention from the real issues of class dominance.

On the Irrelevance of Conventional Methodology for Conflict Propositions

Reasons argues that empirical findings generated by traditional positivist methodology—incredibly equated with functionalism—are not especially relevant for conflict propositions, because the latter are judged more appropriately by their action implications. This irrelevance, in short, derives from what are perceived to be basic and irreconcilable differences between conflict and positive methodologies, with the former stressing ideology and the latter objectivity.

In reply, we argue that ideology and objectivity are necessary components of *both* perspectives, and to assume that they are mutually exclusive is to misunderstand the nature of objectivity as described in Gouldner's (1975) recent essay and to risk a debilitating kind of false consciousness.

The utility of ideas for courses of action is hardly an evaluative criterion that is unique to conflict theory. The premise of scientific inquiry is that we explain in order that we might control, and it is not uncommon for basic essays on the nature of theory to include "pragmatic utility" as a criterion for evaluating theoretical positions (Reynolds, 1971; Schrag, 1967). This point has been strongly emphasized by Gouldner (1970:47-8), who contends that all theory is "normative" and has action imperatives:

every social theory facilitates the pursuit of some, but not all courses of *action*, and thus encourages us to change or to accept the world as it is, to say yea or nay to it. . . . In this sense, every theory and every theorist ideologizes social reality.

Thus, what distinguishes conflict from other perspectives is not that pragmatic utility is

relevant, but rather *what* pragmatic utilities are implied. Durkheim on social solidarity and Marx on social change are not distinguished as empirically relevant in the first instance and normatively relevant in the second. Rather, for both, action implications are manifest—even if the action is to consolidate order.

That empirical evidence is relevant for conflict analysis should be readily obvious to most. The science in Marx's "scientific socialism" is not limited to general theoretical laws, but involves, as well, a painstaking attention to empirical fact when available—as in the variety of *tables* employed to illustrate the "General Law of Capitalist Accumulation." The importance of empirical evidence is clearly implied in the formulation of "testable" propositions by Turk (1969), Chambliss and Seidman (1971) and Davis (1975). Chambliss (1973:2) has recently observed:

A theory . . . answers a specific question and, if it is to be scientifically useful, must be capable of being proved wrong. . . . We choose one theory or another because it has stood the test of empirical research. Data support the theories that stand the test of time and refute the theories that do not.

Finally, to assume the opposition of ideology and objectivity is to make an error that could prove disastrous, not only on scientific grounds but on purely tactical grounds as well. Gouldner (1975) contends that objectivity is "not neutrality" but *openness* in our cognitive processes so that we are able to "face the bad news" and "not exaggerate the good news." The tactical (action) implications of such openness or objectivity is concisely summarized by Gouldner (1975:5):

More specifically, objectivity has to do with the continued openness or access of persons to "hostile" reports; the lack or loss of objectivity is an underestimate of the negative implications of reports; it is an *under-estimate* of our *adversary's strengths* and an *over-estimate* of *ours*.

Thus, the ideology and worldly objectives of conflict theory, in no sense, remove the necessity of objectivity; indeed, it is the latter which serves the former by providing the bases for rational, self-interested, goal-directed behavior.

Essentially one must suppose that, for critical theory, emancipation and truth are not totally identical; one must suppose that truth serves emancipation and life, the part the whole. (Gouldner, 1975:7)

**MANUSCRIPTS FOR THE
ASA ROSE SOCIOLOGY SERIES**

Manuscripts (100 to 300 typed pages) are solicited for publication in the ASA *Arnold and Caroline Rose Monograph Series*. The Series welcomes a variety of types of sociological work—qualitative or quantitative empirical studies, and theoretical or methodological treatises. An author should submit three copies of a manuscript for consideration to the Series Editor, Professor Robin M. Williams, Jr., Department of Sociology, Cornell University, Ithaca, New York 14853.

ITEMS (Continued)

dealing with the role of prior offense record and the nature of the offender-victim relationship in the adjudication of criminal defendants. RONALD A. FARRELL is Associate Professor of Sociology at the State University of New York, Albany. In addition to collaboration with Swigert in the study of differential legal treatment, his current research includes the development and empirical exploration of causal models of social deviance and analyses of the social psychological aspects of dream content. Swigert and Farrell also have collaborated on two recent books: *Social Deviance*, by Farrell and Swigert (Lippincott, 1975) and *Murder, Inequality and the Law*, by Swigert and Farrell (Lexington Books, Heath, 1977).

■ ERIK OLIN WRIGHT (Marxist Class Categories and Income Inequality) is Assistant Professor of Sociology in the Department of Sociology, University of Wisconsin, Madison, where he is also affiliated with the Institute for Research on Poverty. His current research includes an analysis of the class structure of advanced capitalist societies, with particular focus on the role of the state in reproducing and transforming class structure, and a study of the changing definitions of the working class within Marxist theory over the past hundred years. LUCA PERRONE is a candidate for the Ph.D. at the University of California, Berkeley, and Professore Incaricato, Università degli Studi della Calabria and Università Statale di Milano, Italy. His current research interests include social and economic determinants of strike rates in Italy (1950-1970), economic development and labor unions in Southern Italy, and inflation and the "circulation" of petty bourgeoisie in Italy. His book on the logic and techniques of quantitative research with aggregate data is forthcoming (Feltrinelli, Milan).

■ McKEE J. McCLENDON (Structural and Exchange Mobility) is Associate Professor of Sociology at the University of Akron. He is continuing research in the areas of social mobility and status attainment.

■ JAMES C. McCANN (Interpreting Mobility Tables) is Assistant Professor at the Center for Studies in Demography and Ecology, Department of Sociology, University of Washington, Seattle. He is studying the effects of economic growth and fluctuations, military conscription, and the changing sex composition of the marriageable population on the trend in marriage rate in the U.S. over the past seventy-five years.

■ B. F. MEEKER (Sex Roles and Interpersonal Behavior) is Associate Professor of Sociology

at the University of Maryland, College Park. Her current research includes exchange processes in two- and three-person groups. Her most recent book (with R. K. Leik) is *Mathematical Sociology* (Prentice-Hall, 1975). P. A. WEITZEL-O'NEILL is Lecturer in Sociology at the University of Maryland. Her research interests include interpersonal behavior and methods of assessing social impact.

■ DAVID SNYDER (Validity of Conflict Data) is Assistant Professor of Sociology at Indiana University. He is continuing investigation of changes in the form and magnitude of collective violence and industrial strike activity and, with Paula M. Hudis, is working on a comparative and historical study of the sources and consequences of sex and race occupational segregation. WILLIAM R. KELLY is a graduate student in the Department of Sociology at Indiana University. His present research includes a cross-national analysis of fertility differentials, and theoretical and empirical relations between violence and social change.

■ ARNE L. KALLEBERG (Work Values and Job Rewards) is Assistant Professor of Sociology at Indiana University. His current research is in the areas of monetary and nonmonetary forms of inequality in American society, the processes by which people and jobs are matched in industrial societies, and the relationship of work to personal experience.

■ JAMES M. FENDRICH (Keeping the Faith or Pursuing the Good Life) is Professor of Sociology at Florida State University. He is studying former activists (cross-culturally), black city councilmen, and unions in higher education.

■ LEONARD BROOM (A Modest Test of an Immodest Theory) is Professor in the Research School of Social Sciences, Australian National University. He is continuing research with R. G. Cushing in other tests of the functional theory of stratification and comparative studies of ethnic differentiation. He also is engaged in analysis of the second national survey on social stratification and social mobility in Australia. He is co-author, with F. L. Jones, of *Opportunity and Attainment in Australia* (Australian National University Press and Stanford University Press, 1976) and, with Philip Selznick, *Sociology: A Text with Adapted Readings*, (6th ed.), (Harper and Row, 1977). ROBERT G. CUSHING is Reader in Sociology at the Australian National University. Aside from his continuing study of stratification theories, his current research includes deviance and social control, and social differentiation.

Tortillas for the Gods

A Symbolic Analysis of Zinacanteco Rituals

Evon Z. Vogt

Claude Lévi-Strauss called this study of the ancient rites and rituals of a contemporary Mayan community: "A magnificent work, a wonderful achievement which, undoubtedly, sets up a landmark in our studies."

wcb is...

people and ideas

In just 30 years, the Wm. C. Brown Company Publishers of Dubuque, Iowa, has grown from a small entrepreneurship to an industry leader with over 600 titles in print. To fully understand this spectacular growth in such a short time, consider WCB people and ideas . . .

wcb people . . .

are among the most experienced and dedicated in the industry, and our numbers are rapidly growing. WCB experts, such as our editorial and research personnel, know your field and join WCB authors in producing the top-quality publications you need.

This spring WCB will publish 61 new titles in 17 disciplines. Each publication will reflect the painstaking effort of WCB editorial and research personnel to ensure appropriate content, solid research, logical organization, and lucid examples and illustrations for you and your students.

wcb ideas . . .

appear in the form of textbooks. And to further enhance the teaching-learning process, we complement WCB texts with the most complete learning packages available. We now provide more learning activities, practical teaching suggestions,

and testing and resource materials in our comprehensive program of instructor's manuals, test item files, and answer keys than ever before—and they are free of charge. Our helpful student workbooks and study guides furnish more exercises, summaries, and self-tests to assure your students of a sense of direction in the learning process. WCB growth and experience result in a fuller response to your classroom needs.

From a small entrepreneurship to an industry leader through

people . . . ideas

INTRODUCTION TO POPULATION: A SOCIOLOGICAL APPROACH

Judah Matras — Hebrew University, Jerusalem, Israel

Provides a fresh view of the social structural causes and consequences of current population trends. Offers a detailed discussion of match-making, mate selection, and marriage in relation to sociological, social anthropological, and demographic studies. Describes and illustrates sources of demographic data, methods of measurement, and basic techniques of analysis in a clear, concise manner that speaks directly to students.

1977 544 pp. (est.) Cloth \$14.95

ADOLESCENCE: A SOCIAL PSYCHOLOGICAL ANALYSIS, 2nd Edition

Hans Sebald — Arizona State University

Extensive introductory examination of the sociological and historical dimensions of adolescence in America today. Focus is on identity growth; and how social, cultural, institutional, economic, biological, and role-learning influences bear on it. New material includes analysis of the youth subculture and counterculture, effects of the feminist movement, the role of TV and other media, and the "new sexuality," with an update on drug problems.

1977 480 pp. (est.) Paper \$9.95

WORKING: CONFLICT AND CHANGE, 2nd Edition

George Ritzer — University of Maryland

Basic text for Sociology of Occupations, Professions, and related courses. Focus is on the individual in the "workworld" and changes he or she faces, career opportunities, conflicts and modes of conflict resolution, the distinctive problems of minority groups, and the future prospects of work in America. Sociological view of occupational life debunks many myths about the workworld.

1977 448 pp. (est.) Cloth \$13.95

Forthcoming

CRIME IN AMERICA, PERSPECTIVES ON CRIMINAL AND DELINQUENT BEHAVIOR, Second Edition

Edited by **Bruce J. Cohen**, C. W. Post College, Long Island University

This revision of a successful reader provides a comprehensive analysis of the range of criminal behavior, an extensive discussion of the crime problem in the U.S. and the role of the victim.

c. 550 pages c. \$8.95 paper

ISSUES IN RACE AND ETHNIC RELATIONS: THEORY, RESEARCH AND ACTION

Edited by **Jack Rothman**, University of Michigan

This is a unique treatment of the controversial and perplexing inter-group issues confronting American society. Opposing positions are clearly articulated and each issue is examined from three vantage points: theoretical and philosophical considerations; factual and research considerations; policy and practice considerations.

c. 350 pages c. \$6.95 paper

AMERICAN MINORITIES AND ECONOMIC OPPORTUNITY

Edited by **H. Roy Kaplan**, Pitzer College

This book provides current data on the labor force participation of Blacks, Mexican Americans, Puerto Ricans, American Indians, women and older workers. It departs from traditional demographic and statistical approaches by also including analyses of the social psychological impact of work on these groups. The book demonstrates that there is a strong commitment to work among these groups; that they work not only for financial reasons, but place a high social value on being gainfully employed.

The book reviews laws and court decisions which have affected their struggle for equity and analyzes the halting attempts of the Federal Government to implement affirmative action programs and reduce discrimination in the labor force.

NEW FROM PRINCETON

Jewish Identity and the JDL

JANET L. DOLGIN

To understand the situation of the Jewish Defense League in the U.S., Janet Dolgin spent fourteen months with the JDL in Jerusalem and in New York City. In this book she considers how its members relate to each other and to outsiders, and places these relationships in the context of American society as a whole. "... A very fine book. Here is a major contribution to the processes of the creation of history by the analysis of the present itself—a contribution to the understanding of social and cultural action as a meaningful, symbolically conceptualized whole."—*David M. Schneider, University of Chicago* • \$12.50

Tramways and Trolleys

*The Rise of Urban Mass
Transport in Europe*

JOHN R. MCKAY

"In this first comprehensive analysis of the development of the electric streetrailway in Europe from 1880 to 1910, McKay persuasively argues that the industry was more than simply an advance in transport technology. It had, he shows, a truly revolutionary effect in such diverse areas as urban growth patterns, labor unionism, and popular recreation. . . . An original and provocative study, with implications for urban planners today."

—*Library Journal* Illus. \$14.50

Equality and Preferential Treatment

Edited by **MARSHALL COHEN,
THOMAS NAGEL, and
THOMAS SCANLON**

These essays, originally published in *Philosophy & Public Affairs*, consider the moral problems associated with improving the social position of disadvantaged groups. The issues discussed include compensation, liability, victimization, the significance of group membership, the intrinsic importance of racial, sexual, or meritocratic criteria, and the overall effects of preferential policies. A *Philosophy & Public Affairs Reader*

Cloth, \$8.50 • Paper, \$2.95

The Labor Force in Economic Development

*A Comparison of International
Census Data, 1946-1966*

JOHN D. DURAND

"The author brings together in clear organized form all available labor force data on some 100 countries for the two decades following World War II. With this outstanding accomplishment alone, Durand has served well the goals of a solidly grounded demography of modernization/industrialization. . . . His model research monograph [will be] cited again and again by the authors of more narrowly focused regional or thematic studies made possible only by this volume."

—Thomas O. Wilkinson, *Sociology*

"A scathing indictment of the public school system..."

The strength of the book lies in its calling attention to the seriousness of the situation in the first place."—*Library Journal*

"The book's case histories force a look at the human element involved in the rules and regulations of school administration."—*The Booklist*

BARRED FROM SCHOOL:

TWO MILLION
CHILDREN!

by Thomas J. Cottle

\$7.95 at bookstores or direct from

NEW REPUBLIC BOOKS

1220 19th St., N.W., Washington, D.C. 20036

Distributed by E. P. Dutton

THE NEIGHBORHOOD ORGANIZER'S HANDBOOK

Rachelle and Donald Warren. Shows how to identify a neighborhood by its physical and social characteristics and then determine effective means to act within it. Invaluable for community leaders and human service organizations. \$9.95 cl., \$4.95 pa.

THE RADICAL CENTER: Middle Americans and the Politics of Alienation

Donald I. Warren. An in-depth analysis of the political frustration of middle-class radicals. "An excellent analysis of the 'backlash.'" —*Library Journal*. "... must reading for students of voting behavior." —*Sociology* \$12.95 cl., \$4.95 pa.

UNDERSTANDING AND SOCIAL INQUIRY

Fred Dallmayr and Thomas McCarthy, eds. The first anthology in which the major schools of thought on the role and nature of *verstehen*, or interpretive understanding, in social research are represented and brought into dialogue. \$16.95

THE UNITED STATES-MEXICO BORDER: A Politico-Economic Profile

Raul Fernandez. Within a theoretical framework of historical materialism, this provocative study succeeds in giving coherence to the politico-economic development of the U.S.-Mexico border region for the first time. \$9.95

THOSE OF THE STREET: The Catholic-Jews of Mallorca

Kenneth Moore. Traces the Jewish origin and unique traditions of the Xueta community on the island of Mallorca and suggests that the tourist industry may lead to their assimilation into the mainstream of Spanish Catholicism. \$11.95

LIFE AND POLITICS IN A VENETIAN COMMUNITY

Robert H. Evans. The first large-scale investigation of community life in northern Italy, this book spans the years 1866-1975 and emphasizes historical, social and economic influences on present-day political life. \$15.95

NOTRE DAME

Notre Dame, Indiana 46556

RECENT BOOKS FROM HARPER & ROW

FORGOTTEN TRUTH The Primordial Tradition

By Huston Smith, Syracuse University. A brilliant new book by the author of *The Religions of Man* which incorporates Asian religion, psychedelic experience, and humanistic psychology into a comprehensive and exciting new philosophy of comparative religions. "Exceedingly valuable."—*Rollo May*. \$8.95

TO HAVE OR TO BE?

By Erich Fromm. This vital sequel to *The Art of Loving* is a major humanist manifesto which astutely analyzes the pagan greed and violence underlying—and undermining—industrial society. Volume 50 in *World Perspectives*, planned and edited by *Ruth Nanda Anshen*. 2nd printing, \$8.95

CROOKED PATHS Reflections on Socialism, Conservatism, and the Welfare State

By Peter Clecak, University of California, Irvine. In a stunning reconsideration of American culture and politics, the author of *Radical Paradoxes* examines bourgeois tradition in light of the decline of affluence as a central American expectation. \$10.95

OPEN SPACES

Tradition and Change in American Cities

By August Heckscher. The former New York City Parks Commissioner has written a provocative report on the evolution and development of open spaces in American urban growth and planning. Illustrated. \$15.00

THE BLOOD PEOPLE

By Adolf Hungry Wolf. The history and struggle for cultural separateness of this fiercely traditional Blackfeet Indian group is carefully documented by a white man who, many years ago, adopted the Blood People's way of life as his own. 960 pages, profusely illustrated. \$15.00

THE CHILD FROM FIVE TO TEN

Revised Edition

By Arnold Gesell, M.D., Frances L. Ilg, M.D., and Louise Bates Ames, Ph.D. A landmark book, updated to include a rich fund of new information, and vital reading for anyone who shares in the responsibility for the welfare of children. \$15.00 (Coming in March)

CALL THE FINAL WITNESS

The People vs.

Michael R. Thomas

By Melvyn Bernard Zerman. One juror's thoughtful and moving account, in journal form, of the trial of a 17-year-old youth accused of murder—as well as a deliberation of the objective value of the jury system. \$8.95 (Coming in April)

THE VANISHING WHITE MAN

By Stan Steiner. In this eloquent sequel to *The New Indians*, Steiner says that it is the white man, and not the Indian, who will one day vanish from the American West, choked by greed and smog in a land the Indians struggled so long to conserve. Illustrated. \$10.95

New perspectives

THE SPACEFLIGHT REVOLUTION A Sociological Study William Sims Bainbridge

Society has spent one hundred billion dollars on the exploration of space without a conscious decision to do so or a clear purpose behind it. According to Dr. Bainbridge, clever manipulations by a dedicated social movement has taken us to the moon and beyond. This book not only tells the surprising story of the Spaceflight Revolution, but also gives the first social scientific analysis of why it started and how it succeeded. Readers find vivid descriptions of the early rocket pioneers; the German, American, Russian, and British space societies; indifference of science, governments, and the public to space; the truth about science fiction; and much more.

(0 471 04306-0) 1976
294 pp. \$16.95

AN INTRODUCTION TO PROGRAM EVALUATION Jack L. Franklin & Jean H. Thrasher

Argues that program evaluation is possible and is a valuable organizational activity. This text covers the different evaluating techniques; their design and methodologies; problems and pitfalls; and accomplishments and future. It discusses scope, definition, application, and integration from both an idealized and real-world perspective.

(0 471 27519-0) 1976
233 pp. \$12.50

NEW YORK COPS TALK BACK A Study of a Beleaguered Minority Nicholas Alex

A fascinating new study of the attitudes of white patrolmen toward their work, their black colleagues, the Knapp Commission, the political and legal system, and society in general. Based on analyses of in-depth interviews with 42 New York City white ethnic policemen from various precincts, this book concludes that white police officers see themselves as members of a beleaguered minority group, victimized and betrayed by the department, the public, co-workers, the press, the courts, and the PBA.

(0 471 02055-9) 1976
225 pp. \$12.50 cloth
(0 471 02056-7) \$5.95 paper

THE POST-PHYSICIAN ERA Medicine in the Twenty-First Century Jerrold S. Maxmen

Examines the extinction of the physician and the rise of the "medic computer." Dr. Maxmen predicts that in fifty years doctors will be replaced by computers capable of making diagnostic and treatment decisions. He explores the humanity and technology needed, the future of the health care profession, and the organizational issues involved in such a change. An insightful and challenging view for all those in the medical profession or concerned with society's health care problems.

(0 471 57880-0) 1976
300 pp. \$15.95

DOING SOCIAL LIFE The Qualitative Study of Human Interaction in Natural Settings John Lofland

Collates and codifies the achievements of social scientists in deciphering the tactics, ploys, and ruses people use in the social interactions of everyday life. It reviews different interaction strategies while examining face-to-face encounters, social roles, informal groups, and formal organizations. Of interest to anyone concerned with how humans cope and how they devise and construct their conduct.

(0 471 01563-6) 1976
328 pp. \$14.95

ORGANIZATION THEORY Structures, Systems, and Environments William M. Evan

Recognizing the problem of designing and managing large, complex organizations today, this book outlines the latest ideas and models applicable to organization theory. It examines the assumptions, problems, and functions the hierarchy in organizations experiences, and how these affect the structure organization. It also covers the defining, measuring, and changing of the climate within an organization, and principal types of environments such as: the legal system, multinational corporation, the culture of society, and others.

THE FORM OF SOCIOLOGY Paradigms and Crises S.N. Eisenstadt with M. Curelaru

A thought-provoking book that presents an evaluation of the current state of sociological theory, analyzed in the light of major trends of historical development. The analysis covers theoretical developments and stresses the international character of sociology by applying it to the sociological community worldwide. It also examines the sociologist's self-perception and how it is in a state of crisis (and needn't be).

(0 471 23472-9) 1976
386 pp. \$17.95

THE CREATIVE VISION A Longitudinal Study of Problem Finding in Art Jacob W. Getzels & Mihaly Csikszentmihalyi

A longitudinal study and analytic description of the creative process in a real-life setting, this book traces a selected group of artists from school through their careers. The three part structure of the book offers a psychometric description of the young artist; an analytic description of the creative process from "problem finding" to completion of a piece; and the final results which show that young artists emphasizing problem finding over problem solving are more successful. This book is an exciting, informative analysis of the creative process and the role of problem finding in that process.

(0 471 01486-9) 1976
293 pp. \$17.95

PERCEIVING TIME A Psychological Investigation with Men and Women Thomas J. Cottle

Investigating how people perceive and feel about time—personal past, present, personal future, historical past, and historical future—this study attempts to examine the basic definitions of time and the time zones. Each chapter, organized around one or two major perceptions, presents its own inquiry and method for researching a particular perception of time, and a discussion of the findings.

(0 471 17530-7) 1976
267 pp. \$14.95

SEXUAL VARIANCE IN SOCIETY AND HISTORY Vern L. Bullough

The first comprehensive survey of the history of stigmatized sexual behavior—homosexuality, transvestism, and transexualism. This chronologically organized book looks at attitudes toward sexual behavior throughout Western culture. It includes a discussion of changing scientific concepts of sex, several chapters devoted to 20th-century attitudes, and explanations of the reasons for current changes.

(0 471 12080-4) 1976
715 pp. \$25.95

CASE STUDIES IN SPIRIT POSSESSION Edited by Vincent Crapanzano & Vivian Garrison

Here is a collection of 10 detailed case histories of spirit possession—the first of its kind ever published. These studies range in approach from the psychoanalytic to the social anthropological, from the phenomenological to the social strategic, including material from Morocco, Senegal, Egypt, Ethiopia, Sri Lanka, Malaysia, Brazil, Puerto Rico, and the United States. A fascinating book for anyone interested in the analysis of spirit possession and closely related phenomena.

(0 471 18460-8) 1976
approx. 480 pp. \$21.50

MAX WEBER A Biography Marianne Weber

A comprehensive presentation of her late husband's main ideas and contributions to learning, and portraits of scholars, social reformers, politicians, and poets with whom he came in contact. It traces his years as a student, soldier, lawyer, and university professor. Integrated into the narrative are excerpts from Weber's letters written during his travels in Europe and the United States.

(0 471 92333-8) 1975
719 pp. \$21.00

MAKING INEQUALITY The Hidden Curriculum of High School Tracking James E. Rosenbaum

A thoughtful, sociological analysis of how secondary school guidance counseling and educational procedures put students on fixed tracks—often the wrong ones. This study presents readers with a new understanding of the internal operation of school selection, indicates unintended outcomes of that selection, and suggests policy reforms.

A BRIEF SOCIOLOGY SELF-SURVEY

Are you looking for an introductory text that

- ☐ captures the flavor of sociology
- ☐ integrates useful elements from traditional approaches
- ☐ maintains a humanistic attitude but utilizes historical data and quantitative analysis
- ☐ explores new trends in sociology
- ☐ draws on major research findings from related fields
- ☐ offers a rich variety of examples
- ☐ is concise but thorough

We think you'll like PRINCIPLES OF SOCIOLOGY

by William J. Goode, Columbia University

1977, 528 pages, with Instructor's Manual available

Have your students been exposed to the immediacy of sociological fiction?
Would you consider a paperback that

- ☐ uses selections from literature to illustrate key sociological concepts
- ☐ follows the organization of most introductory texts
- ☐ includes selection and chapter introductions that give background information on both the selections and the concepts they illustrate?

**We suggest you consider UNDERSTANDING SOCIOLOGY
THROUGH FICTION**

**by Myles L. Clowers and Steven H. Mori,
both of San Diego City College**

**1977, 256 pages, softcover, with
Instructor's Manual available**

Could a standardized approach to theory help your students organize their learning? How about a book that

- ☐ concentrates on the emergence, context, and evolution of the major types of sociological theory
- ☐ provides models of various theory types and of the theorizing process itself
- ☐ offers a standardized approach to each theorist
- ☐ looks at the social, intellectual, and biographical factors that influence the development of theory
- ☐ incorporates extensive student aids, outlines, and summaries?

We propose SOCIOLOGICAL THEORY: Its Development and Major Paradigms
by Graham C. Kinloch, Florida State University
1977, 284 pages

Would your students benefit from a statistics text that's not intimidating?
One that

- ☐ covers all the statistics a social scientist is likely to use
- ☐ concentrates on helping the student understand the *meaning* of statistics
- ☐ includes information about actually *doing* social research that is rarely found in textbooks
- ☐ is divided into two sections -- Descriptive Statistics and Inferential Statistics -- with regression analysis appearing early
- ☐ covers even the more sophisticated topics with exceptional clarity
- ☐ includes a liberal sampling of real data and applications?

We think you'll both benefit from SOCIAL STATISTICS WITHOUT TEARS
by Allan Johnson, Wesleyan University
1977, 256 pages

Would you like to try a self-paced approach with your students?
Would you like to see brief, self-contained paperbacks that offer:

- ☐ learning objectives
- ☐ self-tests and exercises
- ☐ end-of-chapter quizzes
- ☐ easy-to-handle modules
- ☐ perforated answer keys
- ☐ glossaries
- ☐ suggested readings

Then take a look at the **McGRAW-HILL BASIC SELF-INSTRUCTIONAL GUIDES.**

INTRODUCTORY SOCIOLOGY

A clear, concise survey of fundamental sociology that presents classic topics with a modern orientation. A section on some of the special characteristics of American sociology is included. 1977, 224 pages, softcover.

MARRIAGE AND THE FAMILY

Marriage and family life are seen as social institutions and as a context for relationships between individuals. Topics of current interest include choosing a single life, childless marriages, and continuing growth in marriage. 1977, 224 pages, softcover.

WADSWORTH PUBLISHING COMPANY, INC.

...whose commitment to Sociology
gives you and your students all the advantages...

In the past several years, WADSWORTH Publishing has introduced some very significant textbooks to the Sociology classroom. Among them: *The Practice of Social Research* and *Survey Research Methods*, both by Earl R. Babbie.

And, WADSWORTH was the first publisher to recognize the importance of aging and to introduce an introductory text specifically for that study: *The Social Forces in Later Life*, by Robert C. Atchley.

Our commitment now—as it was then: to provide you and your students with the most workable textbooks and the most current research available in the field of Sociology.

★ (NEW) ★

by EARL R. BABBIE, *University of Hawaii*

SOCIETY BY AGREEMENT: An Introduction to Sociology

An exciting new introductory text...written solely by an experienced and successful textbook writer who is also an acclaimed practitioner in social science research...“agreements” provides the integrative framework allowing students to see how such seemingly diverse perspectives as conflict theory, symbolic interaction, and functionalism relate. Within this framework, the text provides an overview of sociological theory and research; an examination of socialization, culture, and groups; a treatment of institutions; power, social conflict, and change; and, an analysis of mass society.

At the end of each chapter are fictional episodes written by Agnes Riedmann, a trained sociologist and professional short story writer; combined together, they offer a “story within the text” to illustrate the text’s concepts...Text also includes contributed boxed material by sociologists around the country, a comprehensive glossary, annotated additional readings, study questions, photographs, and originally created cartoons...December 1976. Approximately 600 pages. 8¼x9½. Clothbound. Instructor’s Manual. A complete and especially engaging Study Guide is available for students.

★ (AVAILABLE NOW!) ★

by JUDSON R. LANDIS, *California State University, Sacramento*

**the new THIRD EDITION of
SOCIOLOGY: CONCEPTS AND CHARACTERISTICS**

One of the most popular short-core introductory texts available... thoroughly revised and expanded yet retains those features which made the previous two editions so successful... Offers a unique look at the concepts of Sociology with readings from popular and professional sources to illustrate sociological principles... All chapters have been thoroughly updated and in many places expanded... and, the last chapter, "What Is Sociology?", has been totally revised to include more on sociological theories and why they have relevance to undergraduate students. December 1976. Approximately 425 pages. 6½x9¼. Paperbound. Instructor's Manual.

★ (NEW THIS SPRING!) ★

by RONALD L. AKERS, *University of Iowa*

**the new SECOND EDITION of
DEVIANT BEHAVIOR: A SOCIAL LEARNING APPROACH**

by ROBERT C. ATCHLEY, *Scripps Foundation of Gerontology,
Miami University*

**the new SECOND EDITION of
THE SOCIAL FORCES IN LATER LIFE:
AN INTRODUCTION TO SOCIAL GERONTOLOGY**

The most successful introduction of social gerontology... thoroughly revised. 1976. 448 pages. 6½x9¼. Casebound.

by ROBERT C. ATCHLEY and MILDRED M. SELTZER
Scripps Foundation of Gerontology, Miami University

**THE SOCIOLOGY OF THE AGING:
SELECTED READINGS**

A unique collection of readings to give students a ready, convenient access to major ideas about aging... 1976. 291 pages. 6½x9¼. Paperbound.

by JAMES H. SCHULZ, *Florence Heller Graduate School, Brandeis University*

THE ECONOMICS OF AGING

The most current book available on the subject... written specifically for non-economists! 1976. 208 pages. 6x9. Paperbound.

R. Messent*, Female Hormones and Behaviour. *P. Mayo*, Sex Differences and Psychopathology. *J. Archer*, Biological Explanations of Psychological Sex Differences.

1976, 280 pp., \$11.00/£5.00 ISBN: 0-12-453550-X

Statistical Methods for Social Scientists

by ERIC A. HANUSHEK

A Volume in the QUANTITATIVE STUDIES IN SOCIAL RELATIONS Series

Covering contemporary methods of quantitative analysis as used in sociology, economics, and political science, this text shows how to apply statistical methods in estimating and testing social science models. After an introduction to analytical modeling, the book develops simple regression methods for both single equation and multiequation models and their applications. It features coverage of qualitative dependent variables, errors of measurement, and unobserved variables, and also relates the techniques covered to more specialized areas, such as path analysis and factor analysis. The book presupposes only a limited knowledge of statistical methods and matrix algebra; appendices cover the basics of both. The material is presented in modular form to permit flexibility of coverage in both depth and breadth, making the book an ideal text for an introduction to quantitative methods course.

1977, about 375 pp., in preparation ISBN: 0-12-324350-5

Networks of Collective Action

A Perspective on Community Influence Systems

by EDWARD O. LAUMANN and FRANZ U. PAPPI

A Volume in the QUANTITATIVE STUDIES IN SOCIAL RELATIONS Series

This highly innovative study investigates the structure of community influence and decision-making in a West German town (Altneustadt) utilizing sophisticated techniques and quantitative measurements. Part One describes how one can construct a model of the social differentiation of the community population subsystem that describes the relative proximities of a number of population subgroups differing in their rates of social interaction and their characteristic value orientations. Relying heavily on recent advances in network analysis, Part Two describes the incumbents of the community decision-making subsystem and proposes some models describing their differentiated patterns of association in several important types of social relationships. Part Three systematically distinguishes among the various bases of community influence and proposes a model of the processes of converting various influence resources controlled by different elite members into binding collective decisions.

1976, 348 pp., \$18.00/£12.80 ISBN: 0-12-437850-1

Mass Society

by SALVADOR GINER

Dr. Giner traces the history of the concept of mass society from the early thinkers of Greece through Tocqueville, Marx, Nietzsche, Taine, Mannheim, Jaspers, Freud, and Ortega to C. W. Mills, Marcuse and other modern critics. He goes on to examine to what extent 'mass society' is a correct interpretation of the modern world and to what extent it is the brainchild of the fears and anxieties of disillusioned intellectuals and alarmed liberals. The several branches of the theory—the current doctrines about mass politics, mass culture, the levelling down of social structures—are critically assessed. In conclusion practical proposals are made for useful social theorising.

1976, 304 pp., \$14.50 ISBN: 0-12-284350-9

Academic Press Sales Territory: United States and Dependencies

Social Networks

edited by SAMUEL LEINHARDT

A Volume in the QUANTITATIVE STUDIES IN SOCIAL RELATIONS Series

The theoretical notion of social structure can be operationalized using the mathematical concept of a network. This book gathers articles using network theory as a paradigm in anthropology, sociology, perceptual and social psychology, and community studies. Most of the articles need only elementary mathematics and statistics to show the fruitfulness of the network approach for a wide variety of substantive concerns and levels of abstraction. The articles are organized into four parts: Sentiments and Attitudes; Information, Interaction, and Acquaintance; Roles and Transactions; and Methods.

MOSBY
TIMES MIRROR

BECAUSE THERE ARE NO SIMPLE SOLUTIONS.

new Mosby texts can help your students understand the multidimensional aspects of today's social dilemmas.

A New Book! SOCIAL INTERACTION. By Thomas Kando, Ph.D. Oriented toward an historic and humanistic interpretation . . . soundly scientific with thorough documentation and references . . . easy reading—these are the features that make this an outstanding basic social psychology text. The author critically surveys current social psychological paradigms and maintains an excellent balance between sociological and psychological aspects. March, 1977. 366 pp., 30 illus. Price, \$9.25.

A New Book! URBAN SOCIAL CONFLICT. By Arline F. McCord and William Maxwell McCord. This informative new text stresses social conflict within the urban culture. It delves into the development of cities, attitudes produced in an urban environment, and theories for the rise of social conflict in urban areas. Actual case studies from the authors' personal experiences illustrate reform movements, riots and revolutions. January, 1977. 216 pp. Price, \$6.95.

A New Book! AMERICAN SOCIAL PROBLEMS: Challenges to Existence. By William McCord and Arline McCord. Here's where students will find a highly readable and interesting investigation of American social problems. In addition to comprehensive coverage of such common topics as, race, crime, addiction, and suicide, this text focuses more thoroughly than other available sources on homosexuality, women, aging, and death. March, 1977. 292 pp. Price, \$7.95.

SOCIOLOGY WITH A HUMAN FACE: Sociology As If People Mattered. By Robert Marsh Kloss; Ron E. Roberts; and Dean S. Dorn. In this illuminating text, the authors effectively use biographies to humanize sociological abstractions. Topics include: community authority, status, the sacred, alienation, etc. Plus, chapter exercises actively involve students in the process of sociological inquiry. 1976, 324 pp., 6 figs. Price, \$12.50.

A New Book! A SOCIOLOGY OF HEALTH. By Andrew C. Twaddle and Richard M. Hessler. With primary emphasis on sociology rather than health care delivery systems, this innovative new text reflects current developments in the sociology of health field. Some of the special topics featured include: specialized health occupations—faith healing, Chinese-American medicine; organization of health services; and disease and sick people. February, 1977. Approx. 384 pp., 68 illus. About \$9.95.

Just Published . . .

Sociology: Social Science and Social Concern, Third Edition

Ritchie P. Lowry, Boston College

Robert P. Rankin, California State University, Chico

February 1977

Cloth

736 pages

This text introduces beginning students to the basic concepts, methods, and terminology of sociology in a systematic, unified way. The book is organized according to two guiding themes which are highlighted throughout: The primary theme points up the dual nature of sociology — its simultaneous use of rigorous scientific perspectives and methods, and its humanistic way of viewing society. The second theme studies the problem of freedom versus conformity in human society.

Coming Soon . . .

Systems of Society: An Introduction to Social Science, Second Edition

Manuel G. Mendoza and Vince Napoli, both of Miami-Dade Community College

May 1977

Cloth

608 pages est.

This second edition of *Systems of Man* has been carefully updated and revised, while retaining its functional systems approach to the social sciences — anthropology, social psychology, sociology, economics, politics, international relations. Study Guide and Instructor's Manual available.

Being Urban: A Social Psychological View of City Life

David A. Karp, Boston College

Gregory P. Stone, University of Minnesota

William C. Yoels, Indiana University-Northwest, Gary

February 1977

Paper

256 pages

The only book available in urban sociology that examines the social psychology of city life from a symbolic interaction perspective — posing questions typically neglected in most treatments of urban scene. Topics include alienation, anomie, integration, family relations, relations among friends, neighbors, and strangers, etc.

Recently Published . . .

The Social Welfare Institution: An Introduction, Second Edition

Ronald C. Federico, University of North Carolina at Greensboro

1976

Cloth

384 pages

In this totally up-to-date edition, the history, evolution, current problems, and future direction of social welfare as an institution are investigated using social science theory and methodology. The book has been expanded by about one half its original size to include: (1) many additional exhibits; (2) end-of-chapter study questions; (3) new topics; (4) a revised appendix; (5) updated legislative information; (6) chapter expansion and updating throughout.

Facets of Society

Growing Up Forgotten: A Review of Research and Programs Concerning Early Adolescence

Joan Lipsitz, Learning Institute of North Carolina

A Report to the Ford Foundation

Covers research, social institutions, youth-serving agencies, and the juvenile justice systems as they relate to early adolescence. In Press Winter/Spring 1977

Road Hustler: The Career Contingencies of Professional Card and Dice Players

Robert S. Prus, University of Waterloo,

"C.R.D. Sharper"

Examines the world of the road hustler and gives an intimate view of the world of card and dice hustling. In Press Winter/Spring 1977

The Harassed Worker

Carroll M. Brodsky, University of California

Describes the process of harassment and how it is manifested in working situations. 192pp. \$15.00

Psychosocial Counseling in General Medical Practice

Allan Hodges, University of Colorado

Focuses on training doctors in helping general medical patients with social, emotional, and behavioral problems. In Press Winter/Spring 1977

Gamblers and Gambling: Motives, Institutions and Controls

Robert D. Herman, Pomona College

Discusses the phenomenon of gambling within the context of the themes and values of our culture, and examines the relationships between the behavior of gamblers and other practices and institutions in society. 160pp. \$12.00.

Write for full descriptions and a complete catalog.

The Age-Old Problem of Old Age...

AGING IN MASS SOCIETY: MYTHS AND REALITIES

Jon Hendricks and C. Davis

Hendricks — both of University of Kentucky

A detailed, comprehensive description of the many dimensions of aging.

To appreciate the relative character of aging in today's world it is important to have some grasp of where the elderly stood in other times and other places, vis-a-vis the larger social order. Accordingly, the issues of aging are presented with a focus on both individual and societal manifestations, while major themes are explored from an interdisciplinary, and insofar as possible, cross-cultural point of view.

Major sections include: aging in advanced industrialized societies, theories of social gerontology, physiological and psychological changes, health, work patterns, dilemmas of retirement, family life, the aged in the political arena, minority groups in the later years, and the prospects of aging.

1977 544 pp. (est.)

Cloth \$11.95 (est.)

Women, Crime and Criminology

A Feminist Critique

CAROL SMART

Trent Polytechnic, Nottingham

Carol Smart opens up a whole new direction in criminology by investigating the problem of female crime from a truly feminist perspective. She discusses the nature of female criminality, and gives a survey of classical and contemporary studies of the subject. She examines the problems of developing a feminist perspective on the topic.

\$40.50

A Taste of Prison

ROY D. KING and ROD MORGAN

Respectively University of Southampton and University of Bath

The authors describe the conditions for both adults and young persons in Britain who are held in custody before trial or awaiting sentence. Despite the fact that many of these persons will not subsequently be sent to prison by the courts, the conditions they experience are often no better, and sometimes worse than those for people sentenced to imprisonment. The authors discuss the functions of remand in custody within a changing prison system and propose certain improvements in the regime for remand prisoners.

Direct Edition \$7.00

Colonial Urban Development

Culture, Social Power and Environment

ANTHONY D. KING

Brunel University, Middlesex

Focuses on the social and cultural processes governing colonial urban development, and develops a theory and methodology to do this. The author demonstrates how the physical and spatial arrangements characterizing urban development are the unique products of a particular society, to be understood only in terms of its values, behaviour and institutions, and the distribution of social and political power within it.

Illustrated \$20.50

Bad News

THE GLASGOW UNIVERSITY MEDIA GROUP:

Peter Beharrell, Howard Davis, John Eldridge, John Hewitt, Jean Oddie,

Greg Philo, Paul Walton, Brian Winston

Foreword by Professor Richard Hoggart

It is a common belief that television news in Britain is more objective, more trustworthy, more neutral than press reporting. The illusion is exploded in this controversial study, based on exhaustive monitoring of all television news broadcasts over six months, January-June 1975. The authors took as their special subject industrial news broadcasts, and by showing how TV 'favours' certain individuals and institutions denies the neutrality of the news and directs light on the picture of industrial society that TV news constructs.

XXVI

Families and marriage explored in two new books from Addison-Wesley.

One a theoretical approach, one a practical view. Both give undergraduates an opportunity to examine marriage and the family — now and for the future.

THE FAMILY: FUNCTIONS, CONFLICTS, AND SYMBOLS by Peter Stein, Judith Richman, and Natalie Hannon. Analysis of the family from three sociological perspectives — structural-functional, conflict, and symbolic interaction. A combination of classic essays and original writings. Three parts consider the family in a societal context, the internal development of the family, and the family and social change. Inequalities of class, sex role, race, and age are discussed within the framework of the family.

Available March, 1977

THE MARRIAGE DIALOGUE by A. Lynn Scoresby. Practical, functional illustrations (using communication theory) for successful, marital communication. Skills for interpreting marital messages, sexual communication, decision making, meta-communicating, and managing conflict are discussed and techniques for achieving these skills described.

Available March, 1977

New Spring Texts

FOUNDATION FOR SOCIOLOGY: A Self-Learning Text

R. DIANE SHAPIRO, New Mexico State University

Surveys topics traditionally covered in an introductory sociology course and features objectives, procedures, and self-tests for mastery of the chapter content. This personalized system of self-learning allows students to constantly check their own progress and ensures their comprehension of basic sociological principles. Instructor's Manual with two different test forms for each chapter is available.

c. 350 pages Paper 528-68075-7
Instructor's Manual 528-68074-9

SOCIAL CHANGE

ROBERTA ASH GARNER, DePaul University

An examination of the normal and inevitable process of change in individuals, organizations, and societies. The author discusses a theory of social change, its historical perspective, and how it relates to the individual.

c. 456 pages Paper 528-68013-7

Also by the same author . . .

SOCIAL MOVEMENTS IN AMERICA, 2nd Edition

Extensively rewritten, this text is a chronological analysis of American social movements with an emphasis on causes and consequences.

c. 300 pages Paper 528-68054-4

SOCIAL CHANGE AND HUMAN PURPOSE: Toward Understanding and Action

ROLAND L. WARREN, Brandeis University

Systematizes information about attempts to initiate social change on three major levels: organizational change, community change, and societal change.

c. 400 pages Cloth 528-68048-X

URBAN SOCIOLOGY: Perspectives and Applications

ROBERT A. DENTLER, Boston University

Explores the terrain between the discipline of sociology and the professions of urban planning (including education and health care services and community organization in social work). This combination text and reader serves as a concise, practical guide for identifying urban problems and exploring solutions.

c. 500 pages Paper 528-68063-3

**THE DYNAMICS OF SEX AND GENDER:
A Sociological Perspective**

LAUREL RICHARDSON WALUM, Ohio State University

Introduces gender roles in a sociological context, offering a solid basis for understanding concepts dealing with culture, socialization, social control, stratification, and social movements.

c. 350 pages Paper 528-68076-5

New Sociology Readers

**WOMAN IN A MAN-MADE WORLD:
A Socioeconomic Handbook, 2nd Edition**

NONA Y. GLAZER and HELEN YOUNGELSON WAEHRER
both of Portland State University

Twenty-three new articles are featured in this second edition, which continues to offer a basic understanding of the relationship between women's social condition and their economic position. Presentation of contrasting perspectives encourages students to think critically about central issues regarding women.

c. 400 pages Paper 528-68085-4

**NEW PERSPECTIVES ON THE AMERICAN COMMUNITY:
A Book of Readings, 3rd Edition**

ROLAND L. WARREN, Editor, Brandeis University

An assortment of the major theoretical treatments of the American community by the most influential people in the field. This edition includes eight new selections and is the only sociological reader with a strong emphasis on basic theories of communities.

c. 600 pages Paper 528-68077-3

**AMERICAN SOCIETY INC.:
Studies of the Social and Political Economy of the United States
2nd Edition**

MAURICE ZEITLIN, Editor, University of California, Los Angeles

Based upon a juxtaposition of politically relevant social scientific writings from opposing theoretical perspectives, this book stimulates critical inquiry about the most pertinent issues of American society.

c. 544 pages Paper 528-68078-1

RAND MCNALLY COLLEGE PUBLISHING COMPANY

Box 7600, Chicago, Illinois 60680

XXIX

**THE FAMILY, SOCIETY,
AND THE INDIVIDUAL,
Fourth Edition**

William M. Kephart,
University of Pennsylvania
About 640 pages, with Instructor's
Manual. Just published.

Contemporary, revised, expanded, and visually attractive, the new Kephart has optimum appeal for students of marriage and the family. "The Changing Status of Women: Woman's Rights and Women's Liberation" and "Alternative Life Styles" are two of many new chapters.

**UNDERSTANDING SEXUAL
INTERACTION**

Joann S. DeLora,
San Diego State University
Carol A.B. Warren,
University of Southern California
with materials by Carol Rinklieb
and Douglas Kirby
640 pages, with Instructor's
Manual. Just published.

DeLora/Warren is the first text to cover in depth the *behavioral aspects* of human sexuality while still fully treating the physiological-medical aspects. It integrates current research with case studies, and documents sexuality from three perspectives: physiological, psychological, and behavioral.

**SOCIAL PSYCHOLOGY:
The Theory and Application of
Symbolic Interactionism**

Robert H. Lauer and Warren H. Handel,
both of Southern Illinois University
512 pages, with Instructor's
Manual. Just published.

Lauer and Handel introduce social psychology from a symbolic interactionist perspective designed to give students both the materials for understanding human behavior and the stimulus to use those materials for making analyses. It is based on the work of major symbolic interactionists such as Mead and Cooley.

TEACHER'S

**STATISTICAL REASONING
IN SOCIOLOGY, Third Edition**

John H. Mueller, Karl F. Schuessler,
Indiana University;
and Herbert L. Costner,
University of Washington
544 pages, with Solutions
Manual. Just published.

Written for the undergraduate sociology major with little background in algebra, *Statistical Reasoning in Sociology* emphasizes the intuitive understanding of statistical reasoning rather than mathematical derivations. The Solutions Manual includes detailed answers to the questions and problems in the text.

**MANNY:
A CRIMINAL-ADDICT'S STORY**

Richard P. Rettig, Manuel J. Torres,
and Gerald R. Garrett,
University of Massachusetts, Boston
About 256 pages, paper. Just published.

Manny, the autobiography of a former criminal, lucidly describes present-day gang life, heroin addiction, and prison life. Manny Torres's vivid expression of his experiences, coupled with perspective chapters that relate them to theory, widen the scope of study.

DOZEN.

**Twelve
contemporary
texts
explore sociology
twelve ways.**

SOCIOLOGY: *Understanding Social Behavior*

Alan P. Bates and Joseph Julian, both of the University of Nebraska-Lincoln
500 pages, with Instructor's Guide and Resource Manual by Patricia A. Harvey.
1975.

Students learn sociology through authentic sociological activity by means of photographs, questions, project suggestions, a wide-ranging text, and a wealth of assignments.

POPULATION: *The Dynamics of Demographic Change*

Charles B. Nam,
Florida State University,
and Susan O. Gustavus,
University of Cincinnati
320 pages. 1976.

Nam and Gustavus introduce students to the determinants and consequences of demographic change. Population trends are viewed as an integral part of broader societal trends.

AMERICAN EDUCATION: *A Sociological View*

David W. Swift, University of Hawaii,
and eleven contributors
480 pages. 1976.

In a comprehensive analysis, twelve authors present an inside look at American education, each examining particular facets that they have experienced directly.

FAMILY STRUCTURE AND EFFECTIVE HEALTH BEHAVIOR:

The Energized Family

Lois Pratt, Jersey City State College
280 pages, paper. 1976.

Pratt's interdisciplinary text connects the areas of family with those of health and illness and explores the kind of family structure needed to function effectively in contemporary society.

THE AMERICAN CLASS SYSTEM: *An Introduction to Social Stratification*

Daniel W. Rossides, Bowdoin College
480 pages. 1976.

The first text to combine a thorough introduction to social stratification with an extensive analysis of an industrial system of stratification—the American class system.

SOURCEBOOK IN MARRIAGE AND THE FAMILY, *Fourth Edition*

Edited by Marvin B. Sussman,
Case Western Reserve University
430 pages, paper. 1974.

Sussman presents a collection of pertinent articles covering trends in marriage styles and family forms, sex roles, socialization, theoretical perspectives, and empirical research.

AN INTRODUCTION TO THE SOCIOLOGY OF LEARNING

Sarane S. Boocock,
Russell Sage Foundation
370 pages. 1972.

A comprehensive study, Boocock's text evaluates past research, reports on present efforts, and sets guidelines for future work.

For adoption consideration, request examination copies from your regional Houghton Mifflin sales office.

SOCIAL PROBLEMS

The Contemporary Debates

Second Edition

John B. Williamson Jerry F. Boren Linda J. Evans

Boston College

Merrimack College

Central Connecticut State College

This successful text-reader examines current social problems in a debate format that allows proponents of various perspectives to speak for themselves. In the new Second Edition the editors have added debates on busing, affirmative action, gay rights, health, and the value of a college education. They have also substituted newer selections in debates carried over from the first edition. Each of the sixteen debates is preceded by substantive introductory material that puts the debate into a broader sociological context and discusses the editors' reasons for selecting that particular issue. All of the introductions were revised for this Second Edition. A manual of test questions is available.

Paper approx. 512 pages February 1977 \$7.50 tent.

FACE TO FACE

The Individual and Social Problems

John Perry Erna Perry

Both at Cuyahoga Community College

John and Erna Perry's new introductory text brings students face to face with issues they will confront in their daily lives. The Perrys see social problems as resulting from dysfunctions in institutions, the social system, and the individual. Focusing on individual experience, the authors' personal style and approach form a bridge between broad sociological issues and the specifics of everyday life. The text includes numerous built-in learning aids and enrichment material, and it is accompanied by both a Study Guide and an Instructor's Manual.

Cloth 560 pages 1976 \$11.95 (Study Guide: \$4.95)

CRISIS IN AMERICAN INSTITUTIONS

Third Edition

Jerome Skolnick

Elliott Currie

University of California, Berkeley

In the new Third Edition of this widely-used reader 50% of the selections are new. The editors have added new chapters on imperialism, corporate power, environmental destruction, work, and social services. They have also revised and expanded the introductory essays that accompany each chapter, and have strengthened their treatment of topics like sexism and inequality.

Paper. 608 pages 1976 \$6.95

XXXIII

THE SOCIOLOGICAL PERSPECTIVE

Introductory Readings Fourth Edition

Scott G. McNall

University of Kansas

THE SOCIOLOGICAL PERSPECTIVE was designed to help students understand what sociology is, which concepts are most significant in studying society, and how sociologists go about their work. In the new Fourth Edition the section on institutions has been expanded to include the economy and educational institutions. Sections on doing sociology and interaction in everyday life have been added. The section on population now includes articles that show how changing attitudes about family size, etc., relate to women and work. Thirty-five of the fifty-seven articles are new. An Instructor's Manual with test questions is available.

Paper approx. 512 pages February 1977 \$6.95 tent.

THE RESEARCH CRAFT

An Introduction to Social Science Methods

John B. Williamson David A. Karp John R. Dalphin

Boston College

Boston College

Merrimack College

This social research methods text is distinctive from others in its field in two important ways. First, it offers comprehensive coverage of alternative research methods. Second, it emphasizes first-hand experience with each of the methods discussed, through a series of exercises that can be carried out individually or in small groups. In Part One of the text the authors discuss central issues—measurement, objectivity, sampling, and ethical considerations—which are pertinent to all social research, regardless of the specific approach selected. Part Two includes separate chapters on the nine methods most frequently employed by social scientists, plus a final chapter on quantitative data analysis methods.

Cloth 468 pages January 1977 \$11.95 tent.

CITY SCENES

Problems and Prospects

J. John Palen

University of Wisconsin, Milwaukee

CITY SCENES is an integrated collection of significant articles and essays on contemporary problems of the urban scene. The provocative, highly readable selections reflect developing concerns of the late '70s. The book's eight chapters are divided into three main sections, dealing in turn with: the overall status of contemporary city and suburban life; the persistent problems of crime, ethnicity, and race; and the spectre or vision of the future. The chapters are linked by extensive editorial commentary that broadens the context and supplies background material.

Paper approx. 380 pages February 1977 \$6.95 tent.

FAMILY IN TRANSITION

Rethinking Marriage, Sexuality, Child Rearing, and Family Organization

Second Edition

Arlene Skolnick

Jerome H. Skolnick

Since its publication several years ago, *FAMILY IN TRANSITION* has been one of the most influential books in the marriage and family field. Covering four key topics—the family idea, the politics of sex and marriage, the politics of child rearing, and the politics of family and household organizations—it includes readable yet scholarly selections drawn from history, biology, sociology, psychology, and anthropology. The new Second Edition retains the most successful elements of the original, including its emphases on the nature of the family, sexuality and sex roles, social change, and childhood and parenthood. There are new emphases, however, on "Variations in Household and Life Style," "Men's Roles," "Women's Roles," and "The Social Meaning of Sexuality." Thirty-nine of the forty-three readings are new to this edition. An Instructor's Manual is available.

Paper approx. 512 pages February 1977 \$6.95 tent.

HUMAN SEXUALITY IN TODAY'S WORLD

John H. Gagnon

State University of New York, Stony Brook

HUMAN SEXUALITY IN TODAY'S WORLD is the only reader that provides a coherent approach to human sexuality. Articles have been carefully selected from such popular sources as *Psychology Today*, *Today's Health*, and *The New York Times* to provide insight into all areas of sexuality—V.D., contraception, abortion, new sexual lifestyles, sexual minorities, heterosexuality, sex therapy, sex uses and abuses of women, and our erotic environment. Within each chapter, basic ideas are introduced and progressively developed through the sequence of articles to provide maximum insight into the topic being discussed and maximum impact on the student.

Paper approx. 350 pages March 1977 \$6.95 tent.

SCENES FROM LIFE

Views of Family, Marriage, and Intimacy

Judy Blankenship

Genesee Community College

A new text-reader that skillfully combines selections from the popular press, fiction, non-fiction, poetry, and sociological writings. It's organized around nine sections which roughly parallel the life cycle: The Single Life, Sexual Variations, Marriage, Population/Birth Control, The Family, Childhood/Parenthood, Challenging Sex Roles, Alone, and Aging/Death. Substantial editorial material helps students understand the significance of each element in the life cycle.

Paper 528 pages 1976 \$6.95

NEW FOR

Second Edition

CORRECTIONAL INSTITUTIONS

*Edited by Robert M. Carter, Daniel Glaser, University of Southern California;
and Leslie T. Wilkins, State University of New York, Albany*

This well balanced Introduction to corrections comprises thirty-eight articles — of which twenty-seven are new to this edition — that cover the history and current status of prisons and prison systems, with particular emphasis on the problems of the

inmate. While retaining the structure of the first edition, this new edition stresses new approaches to correction, including community programs and innovative programs within prisons.

571 pages/1977/paperbound, \$7.95

Lippincott

XXXVI

ESSENTIAL STATISTICS FOR SOCIAL RESEARCH

Michael A. Malec, *Boston College*

Designed for students with limited mathematical background, this concise text provides enough of the basic matter of statistics to enable them to read sociological literature with some appreciation of the

function and significance of statistics. The content of this helpful book is limited to those statistics regularly used by sociologists.

about 250 pages/early 1977/paperbound

Fifth Edition

MARRIAGE AND FAMILY DEVELOPMENT

Evelyn Mills Duvall, *Family Life Consultant*

Completely rewritten and updated, this new edition includes data and findings from the latest research in the areas of marriage and family. New material includes such topics as: alternative forms of marriage; marriage contracts; sex differences and gender roles; marital options;

changing sexual attitudes and behavior; death of family members; dissolution of marriage; social change; and racial and ethnic differences. The life-cycle approach has been retained; keyed references, tables and charts amplify the text.

about 400 pages/March 1977/clothbound

OFFICIAL DEVIANCE

Readings in Malféasance, Misfeasance, and Other Forms of Corruption

*Edited by Jack D. Douglas, University of California, San Diego;
and John M. Johnson, Arizona State University*

Comprehensive and up-to-date, the articles in this collection range over sociological analyses, government reports, historical and journalistic accounts, and comments by participants. Three initial articles define political corruption and show how criteria vary for defining corrupt

behavior in different times and societies. Coverage includes Watergate, CIA and FBI scandals, the NYC fiscal crisis, Kent State, Attica, and Washington lobbying. Each section has a brief introduction, and the last section offers proposed solutions to problems of official deviance.

about 375 pages/early 1977/paperbound

FAMILY STRUCTURE AND INTERACTION

A Comparative Analysis

Gary R. Lee, *Washington State University*

In this book the author demonstrates how comparative research has contributed to theory development in the sociology of the family. The focus throughout is on knowledge about family structure and behavior which has been generated, refined or ex-

tended by comparative research. Organization is topical, rather than systemic, with the objective of explanation rather than description. Controversial topics include premarital relations, sex roles, and the relationship of roles to conjugal power.

about 360 pages/early 1977/clothbound

BLACK SEPARATISM AND SOCIAL REALITY: RHETORIC AND REASON

Edited by Raymond L. HALL,
Dartmouth College

The only work which deals exclusively with the subject of black separatism, viewed from a socio-historical perspective, BLACK SEPARATISM AND SOCIAL REALITY is a collection of largely original articles by contributors representing a range of perspectives, ideas, orientations and ideologies. With an introduction by the author relating the black separatist movement to social reality, this work presents a new perspective on the subject. Among the fundamental issues it raises are:

- Should blacks seek their political destiny apart from white Americans?
- Should white liberals be eschewed as allies, as merely "covert racists"?
- Can economic growth within the black community eventually lead to true "black power"?
- Is the destiny of black Americans linked intrinsically with that of Africa, or, as is the view of some, must Africans pursue their own fate separately from their "American cousins"?
- Should a "cultural revolution" among blacks precede any other form of liberation?

Although no one can answer these questions with assurance, this collection of articles by such contributors as Stokely Carmichael, Richard A. Long, Thomas Pettigrew, Robert S. Browne, Imamu Ameer Baraka and others offers a unique opportunity for both blacks and whites to explore the diverse viewpoints on the subject and the role of separatism in our society today.

TOWARDS THE ELIMINATION OF RACISM

Edited by Phyllis A. KATZ, CUNY

"...a goldmine of essential information."

From a review by Robin M. Williams, Jr., Cornell University, in Science

"The first major handbook of research on racism since Allport's classic work of two decades ago."

Marshall Segall, Syracuse University

Written by individuals who are active and current researchers in the field of race relations, TOWARDS THE ELIMINATION OF RACISM is a collection of the current, salient literature on racial attitudes and race relations. Findings relevant to attitude and behavior change are emphasized, and contemporary approaches to racism are compared with more traditional views. Analyses of changes in the media's portrayal of minority groups and an evaluation of white resistance to civil rights programs are also included. The final chapter delineates legal remedies available to those who are victims of racism.

Published in cooperation with The Society for the Psychological Study of Social Issues.

Classic

Masters of Sociological Thought Ideas in Historical and Social Context

Second Edition

LEWIS A. COSER,
State University of New York at Stony Brook

For the forthcoming Second Edition of this classic volume, Professor Coser has added two new chapters examining the life and work of Pitirim A. Sorokin and William I. Thomas and Florian Znaniecki, and a new concluding survey of the major American sociological theorists of the past several decades. The addition of this material to the original chapters on Comte, Marx, Spencer, Durkheim, Simmel, Weber, Veblen, Cooley, Mead, Park, Pareto, and Mannheim means that the book now presents an even more impressive gallery of sociological masters and a more inclusive survey of the development of sociological thought.

The new chapters on Sorokin and on Thomas and Znaniecki parallel the organization of the book's original chapters: they include an initial summary of the theorist's work that incorporates much quoted material; a brief sketch of the man's life and professional career; a consideration of the intellectual context in which the theorist's work appeared; and a final section dealing specifically with the *sociological* influences on the man's work — in effect, applying sociological methods to the study of sociologists themselves. The concluding survey, "Recent Trends in American Sociological Theory," of necessity departs from this structure; here, Professor Coser surveys the influential movements in American sociology during the past 40 years — functional analysis, micro-sociological and conflict theories, symbolic interactionism, dramaturgical analysis, and labeling theory — and the major theorists associated with these trends.

Challenging

Social Change in the Twentieth Century The Impact of a Changing World System

DANIEL CHIROT,
University of Washington, Seattle

Daniel Chirot's challenging new introduction to comparative sociology is the first book of its kind to take a world systems approach to the subject — one whose central theme is the economic and political interrelatedness of every part of the world. Drawing particularly on the work of Immanuel Wallerstein, the author develops — through a judicious blend of theory, fact, and generalization — an overall view of social change based on the interactions of nations since 1900. His book is clearly written and thoroughly accessible to undergraduates; no background in economics, political history, or statistics, other than that provided by the text itself, is necessary to appreciate Professor Chirot's clearly stated and well documented thesis.

Revolution & Reaction in Cuba 1933-1960

*A Political Sociology
from Machado
to Castro*

by **Samuel Farber**

Applying the techniques of the sociological method to his analysis of the historical events—and thus carefully examining both Cuban society and Cuban politics during the period of 1933-1960—Samuel Farber argues against the commonly accepted thesis that the Castro revolution was created by the revolt of a particular class. He categorizes it instead as *Bonapartist* in the Marxian sense of the word. That is, as having had a revolutionary leadership not directly responsive to any single class, but rather manipulative of all classes since none alone was strong enough to dominate. Farber's work provides a new look at Castro's rise to power.

SOCIAL PROBLEMS IN AMERICA

SOCIAL PROBLEMS IN AMERICA approaches social problems from the same social structural viewpoint as the author's well-known AMERICAN SOCIETY, while offering more comprehensive coverage and numerous pedagogical aids.

The text analyzes social problems associated with the structure of social institutions, the stratification system, the organization community, and the deviance regulating system in America. Included are chapters on sexism in America; the family and alternative structures, the economy, and deviant subcultures.

OUTSTANDING PEDAGOGICAL AIDS:

- Marginal notes throughout each chapter underscore important points and can be used for quick, easy review.
- Human interest essays depict real-life examples of social problems.
- "Sociological Insights"—boxed inserts—supplement the text with interesting applications.
- Numerous photographs and line drawings highlight the presentation.

Tentative: 544 pages; \$11.95. February 1977. ISBN 0-06-046717-7. The *Instructor's Manual* provides discussion questions, lecture notes, and multiple-choice, essay, and true-false questions.

AMERICAN SOCIETY

PROBLEMS OF STRUCTURE SECOND EDITION

Professor Turner's concise, well-written paperback text has been heralded for providing a structural framework within which students can organize their thoughts about today's social problems. In a succinct fashion, AMERICAN SOCIETY gives students an understanding of how contemporary social problems are built into the structure of American society.

The new edition presents more data and statistics as well as carefully balanced coverage of a wide variety of social problems. 306 pages; \$8.95/paper. August 1976. ISBN 0-06-04606-1.

To request examination copies, write to Lilian Schein, Dept. 389.

TRENDS IN RACIAL INEQUALITIES: HAVE THE GAINS OF THE 1960s DISAPPEARED IN THE 1970s?

REYNOLDS FARLEY

University of Michigan, Ann Arbor

American Sociological Review 1977, Vol. 42 (April):189-208

Since the end of the Depression the black population has become urbanized, and black leaders increasingly have stressed civil rights grievances. Federal courts have overturned many segregationist practices, and Congress has enacted encompassing civil rights legislation. The nation's economy expanded rapidly in the 1960s, and economic growth may account for the improvements in the status of blacks registered in that decade. We would anticipate that the improvements of the 1960s would be negated in the recession of the 1970s. Investigation of recent trends in education, employment, occupations, family income and personal earnings shows that gains made in the 1960s did not disappear. Indeed, racial differences attenuated in the lean 1970s just as they did in the prosperous 1960s. The changes of the post-Depression period apparently mean that even during a pervasive recession blacks did not lose the gains they previously experienced. Despite these improvements, racial differences remain large and will not disappear soon.

Since the end of the Depression, four major trends in race relations are evident. First, blacks left the rural South and are now geographically dispersed. In 1940, 80 percent of the nation's blacks lived in the South and almost two-thirds of the southern blacks were in rural areas. By the mid-1970s, the proportion in the South decreased to 53 percent and a higher proportion of blacks than whites lived within metropolitan areas (U.S. Bureau of the Census, 1943a: Table 3; 1975a: Tables 3 and 4). There has been a concomitant change in occupations as the proportion of employed blacks working on farms fell from 32 percent to two percent (U.S. Bureau of the Census, 1943b: Table 62; 1975a: Tables 48 and 49).

Second, black demands for civil rights have increased. During the early 1940s, A. Philip Randolph led the struggle for equitable jobs. A decade later the NAACP won court battles concerning equal opportunities in employment, housing and schooling and, in the 1960s, Martin Luther King focused the nation's attention upon the civil rights grievances of southern blacks (Franklin, 1967:ch. XXIX).

Third, governmental actions to imple-

ment the Thirteenth, Fourteenth, and Fifteenth Amendments became more numerous. At the outset of World War II, President Roosevelt established a Fair Employment Practices Commission and, after the war, President Truman's Executive Order 9981 sought to integrate the armed forces. Supreme Court rulings in the 1950s overturned the separate-but-equal principle and outlawed many discriminatory practices. The Twenty-Fourth Amendment encouraged the participation of blacks in federal elections. The Civil Rights Act of 1964 forbade discrimination in employment and public accommodations, sought to end school segregation and created the Equal Employment Opportunity Commission. After the assassination of Dr. King, Congress enacted a civil rights law forbidding discrimination in the sale or rental of most housing. Many programs in the 1960s were designed to assist the poor—especially blacks—by providing federal monies for local schools, for urban renewal and for job training.

Finally, white attitudes and beliefs about blacks have become less prejudicial. Between the early 1940s and the

mid-1960s, the proportion of national samples of whites who believed that Negroes were as intelligent and educable as whites rose from about 40 percent to 80 percent (Hyman and Sheatsley, 1964:6). The proportion of whites who said they would not be disturbed if a Negro with the same income and education moved onto their block rose from 35 percent in 1942 to 84 percent in 1972. During the same span, the proportion of whites who claimed that children of both races should attend the same—not separate—schools increased from 30 to 84 percent (Sheatsley, 1966:219-22; National Opinion Research Center, 1972: questions 39 and 46).

Each of these trends should have reduced the traditional isolation of blacks and may have allowed them to compete more equitably with whites. At the macro level, changes are evident. Racial differences in educational attainment have gradually decreased, more than a few blacks now work at the occupations once reserved to whites and, since the end of World War II, the average income of black families has risen slightly more rapidly than that of white families (Levitan et al., 1975: chs. 2, 3 and 4).

These changes occurred during an era of general economic expansion. Thirty years ago, Myrdal (1962:401) noted the marginal status of blacks and stressed that opportunities for advancement depended upon national economic trends. Rose (1964:313) elaborating upon Myrdal's findings, observed that blacks made gains during World War II but he argued, "The real test of whether Negroes have been granted equal economic opportunity will come if and when America again faces mass unemployment." During the 1960s, economic growth rates were high and conditions favored the incorporation of marginal groups. The 1970s differ markedly. Not only has the unemployment rate risen (U.S. Bureau of Labor Statistics, 1976: Table A-1) but real family income has declined (U.S. Bureau of the Census, 1976c: Table 11). At the same time, support for civil rights legislation has waned, no new civil rights acts have been passed and anti-poverty programs have been dismantled.

If the 1940 to 1970 changes altered the

status of blacks and incorporated them into important positions in the nation's economic and political structure, we would expect that even during a recession blacks would maintain the gains made during the prosperous 1960s. On the other hand, if the gains of the 1960s were merely the consequence of economic growth and did not alter the marginal status of blacks, we would expect these gains to be negated.

This analysis investigates whether the black gains of the 1960s disappeared in the 1970s. Data concerning educational attainment, employment, occupational prestige, income and earnings will be examined.

TRENDS IN EDUCATIONAL ATTAINMENT

Throughout this century there has been a secular trend toward greater educational attainment. Although this involved both races, the years of schooling completed by blacks have always been fewer than those completed by whites (Folger and Nam, 1967: Table V-6; Hauser and Featherman, 1976: Table 8). Figure 1 indicates the educational attainment of the population age 25 and over. These data, and those analyzed in later sections, were gathered in decennial censuses or in the Census Bureau's monthly Current Population Survey. Wherever possible, data for the white and black population have been used. Prior to 1968, many tabulations were made for nonwhites rather than for blacks and, when necessary, these have been analyzed.

Figure 1 shows the first and third quartiles of educational attainment and a time series of indexes of educational dissimilarity calculated from educational distributions of eight categories. This measure of the overlap of the black and white distributions takes on its minimum value of zero when the distributions are identical. If, on the other hand, all whites had attainments greater than any blacks, the index would equal 100—meaning no overlap of the distributions and maximum dissimilarity.

Racial differences in attainment gradually diminished after the Depression. In 1940, the difference at the first quartile

TRENDS IN RACIAL INEQUALITIES

191

Figure 1. First and Third Quartiles of Educational Attainment and Indexes of Educational Dissimilarity, 1940 to 1975, Population Age 25 and Over

U.S. Bureau of Census, Census of Population: 1950, P-C1, Table 114; Census of Population: 1960, PC(1)-1D, Table 173; Current Population Reports, Series P-20, Nos. 45, 77, 99, 121, 138, 158, 169, 182, 194, 229, 243, 274 and 295.

point was about four and one-half years of schooling but, by the late 1960s, the difference was under three years. At the other extreme, the racial gap at the third quartile point—which was about four years in 1940—decreased to less than one year in the late 1960s for both sexes. The trend toward smaller racial differences in attainment persisted into the 1970s. The indexes of dissimilarity continued their decline and, at present, educational distributions overlap more than at previous dates.

Changes in the attainment of adults occur primarily because older individuals with few years of schooling are replaced by younger people who have greater attainment. Education trends can be studied further by analyzing the attainment of the birth cohorts recently completing schooling. Table 1 indicates attainment at ages 25 to 29 using the same measures as Figure 1.

Over time, racial differences as assessed by the index of dissimilarity declined, and the first quartile points of the black and white educational distributions are closer now than they were in the 1960s and very much closer than thirty years ago. This occurred primarily because of a racial convergence in secondary school completion. Shortly after World War II,

approximately two-thirds of the whites compared to one-third of the nonwhites finished twelve years of education (B. Duncan, 1968: Table 26). Blacks have pretty much "caught up" with whites at this level and, among those in their early twenties today, 85 percent of the whites and 72 percent of the blacks completed high school (U.S. Bureau of the Census, 1976a: Table 1).

The racial gap at the third quartile point has grown larger among both sexes. This occurred because, throughout most the post-World War II span, increases in college enrollment were greater among whites than among blacks. In 1969, 36 percent of white men 18 to 24 were enrolled in college compared to 16 percent of black men—a difference of twenty percentage points which was twice the difference recorded in the Census of 1950 (U.S. Bureau of the Census 1953: Tables 104 and 112; 1970a: Table 1). As a consequence, the racial difference among those completing college widened.

Future trends in educational attainment depend largely upon college enrollment rates. If black enrollment rates approach those of whites, the long-term trend toward educational convergence will continue. Between 1969 and 1975, college enrollment rates of blacks increased more

Sources: U.S. Bureau of the Census, Census of Population: 1950, P-C1, Table 115; Census of Population: 1960, PC(1)-1D, Table 173; Census of Population: 1970, PC(1)-D1, Table 199; Current Population Reports, Series P-20, No. 158, Table 4; No. 295, Table 1.

than those of whites, suggesting that racial difference in attainment may attenuate (U.S. Bureau of the Census, 1970a: Table 1; 1976b: Table 6). The social and economic processes which brought about a convergence of attainment at the secondary school level in the 1950s and 1960s may have similar effects on college attendance in the 1970s (Hauser and Featherman, 1976:110-6).

TRENDS IN UNEMPLOYMENT AND EMPLOYMENT

If blacks occupy a marginal position in the nation's economy, they would be the last hired and the first fired. In a period of economic contraction such as the 1970s, we would expect unemployment to rise more rapidly among blacks than among whites.

Trends in Unemployment

Unemployment rates are calculated for those who are in the labor force. If a person 16 or over worked for pay or was temporarily absent from a job because of illness, a vacation or a strike, that person was classified by the Census Bureau as employed. The unemployed population includes those persons who did not work but made specific efforts to find jobs, those waiting to be recalled from lay-offs and those awaiting the start of new jobs. Not all persons are in the labor force. Those who have given up the search for work, retirees, homemakers and many students are not members of the labor force (U.S. Bureau of Labor Statistics, 1976:130). Figures in this section refer to whites and nonwhites and exclude military personnel. This exclusion affects rates for young men since, in 1975, seven percent of the male population 16 to 24 were in the armed forces (U.S. Bureau of Labor Statistics, 1976: Table A-3). These data refer to annual averages except for 1976, when data for the first five months were used.

Data concerning unemployment are available from 1948 to the present. The nation's unemployment rates declined during the Korean and Vietnamese wars

but rose in other periods. (See Figure 2 which shows the percentage of the nation's total labor force unemployed for each year.) This rate climbed rapidly in 1974, and in 1975 it was at the highest level since the nation mobilized for World War II (U.S. Bureau of Labor Statistics, 1976: Table 1).

Descriptions of the employment status of nonwhites frequently focus upon high unemployment rates. Throughout much of the post-World War II era, the unemployment rate for nonwhite men has been twice as great as that for white men, as indicated in Figure 2. Since unemployment rates vary by age, these rates were standardized for age. Then the ratio of nonwhite to white unemployment rates was determined and these ratios are plotted in Figure 2.

From the mid-1950s to the late 1960s, the ratio of unemployment rates among men persisted at about two to one. At the end of the 1960s, the economy expanded and the ratio of unemployment rates decreased to the levels observed during the Korean War. During the 1970s, unemployment increased more rapidly among nonwhites than among whites. The proportion unemployed went up from 5 to 13 percent among nonwhite men between 1969 and 1975 while it increased from 3 to 7 percent among whites (U.S. Bureau of Labor Statistics, 1976: Table 1; 1970: Table A-1). The ratio of unemployment rates rose and much of the improvement registered in the late 1960s was negated. Nevertheless, this ratio in the mid-1970s is lower than it was around 1960 when the national unemployment rate was much smaller.

Racial differences in unemployment have been smaller among women than among men. The ratio of nonwhite to white unemployment rates has been less than two to one for most of the post-World War II period and, even during the recession of the 1970s, the rise in unemployment was no greater among nonwhite women than among white women. Apparently, black women have maintained their employment position *vis-à-vis* whites and, on this measure, the gains of the 1960s have not diminished.

Figure 2. National Unemployment Rate and Ratio of Unemployment Rate of Nonwhites to That of Whites, 1948 to 1976, Population Age 16 and Over

Trends in Employment

Unemployment rates may inaccurately reflect labor force conditions since numerous unemployed individuals may become discouraged, give up the battle to find work and drop out of the labor force. Nonparticipation in the labor force also may indicate the relative position of blacks. To analyze these trends, we studied changes in the proportion of population who held a job, that is, employed persons as a proportion of the total adult

population. If one is interested in the generation of income and the elimination of poverty, it may be more meaningful to consider employment trends rather than unemployment trends (Shiskin, 1976). Figure 3 presents the age-standardized proportions employed for the white and nonwhite civilian labor force. No distinction has been made between workers who held part- or full-time jobs.

The data for men show modest decreases in the proportion of white men at

^aThese data standardized for Age. See text.

Figure 3. Proportion Employed among the Population Age 16 and Over, 1948 to 1975 *

work. This occurred, in part, because of a sharp reduction in the proportion employed among men over 55—a change undoubtedly brought about by expansion of Social Security benefits and private pension plans. At younger ages there have been small declines in labor force participation rates and substantial year-to-year fluctuations in unemployment.

At all dates, the proportion employed has been lower among nonwhite than among white men and the proportion at work has declined since the early 1950s. Among nonwhites, labor force participation rates have decreased not only among men over 55 but among those at younger ages. For instance, in 1953, about 96 percent of the nonwhite men 25 to 55 were labor force participants, but this figure dropped to 89 percent in 1975 (U.S. De-

partment of Labor, 1975; Table A-4; U.S. Bureau of Labor Statistics, 1976: Table 1). At ages 16 to 24, labor force participation rates once were approximately equal for white and nonwhite men but this too changed, and the proportion of young men in the labor force is now substantially lower among nonwhites than among whites.

In the mid-1970s, the trend toward lower labor force participation combined with high unemployment rates to produce sharp decreases in the proportion of nonwhite men with jobs. As Figure 3 indicates, in 1975 and early 1976 about three-quarters of adult white men, but less than two-thirds of nonwhite men were employed, and racial differences on this indicator are now larger than before.

Decreases in employment adversely af-

fect the income of nonwhite families. However, it is necessary to know more about the activities of men who are not in the labor force. If fewer men work because they attend school or are retired, we would draw different conclusions than if they do not work because jobs are unavailable.

Since 1967, the Bureau of Labor Statistics has tabulated the activities of persons not on the labor force. They are classified as keeping a home, going to school, unable to work or not working for "other reasons." If the lack of economic opportunities accounts for the decreasing proportion of nonwhite men at work, we would anticipate that a growing proportion of nonwhite men would not be in the labor force because of "other reasons," but the data are not consistent with this speculation. In the 1970s, there has not been a sharp increase in the proportion who are not in the labor force because of "other reasons." Rather, there has been a modest rise in the proportion in this category, as well as increases in the proportion unable to work or going to school (U.S. Bureau of Labor Statistics 1976: Table 1; 1970: Table A-1).

Employment trends among men cannot be readily summarized. The pattern of nonwhite unemployment rates being twice those of white rates emerged in the mid-1950s (Killingsworth, 1968:20-2). This ratio temporarily fell below two to one in the later 1960s, but climbed back to about two to one in the present decade. This, however, is only one facet. Since the 1950s, labor force participation has decreased among nonwhite men and, thus, the racial differences in the proportion of men who have jobs has increased. On this indicator, black men appear to fall behind white men in both prosperous and lean times.

Figure 3 also contains information about employment trends among women. The fraction of nonwhite women holding jobs has changed little in the last two decades, and at all dates just over 40 percent were employed. The recession of the mid-1970s reduced employment by a modest amount. A different trend characterizes white women, for the proportion at work has risen about one-half a percent-

age point each year since the 1950s. Traditionally, a higher proportion of black than white women have worked (Bancroft, 1958:30-3; Bowen and Finegan, 1969:91). This difference has disappeared and, in 1975, the proportion at work was slightly higher for white than for nonwhite women.

OCCUPATIONAL CHANGE

Since the 1950s there has been a modest upgrading of the occupations pursued by white workers, but among nonwhites there has been a more dramatic shift into higher status jobs and thus racial differences in occupational prestige have declined.

Figure 4 shows trends in the occupations of employed workers. The decennial censuses and monthly labor force reports classify workers into eleven major categories. Persons in each category have been assigned a prestige score using the system developed by O. D. Duncan (1961, ch. 6; Hauser et al., 1975: Table 1). At the lower end, laborers were assigned a score of 7 while professionals, at the other extreme, were scored 75. Figure 4 shows the first and third quartiles of the occupation prestige distribution. To assess the similarity of the white and nonwhite distributions, indexes of occupational dissimilarity also are presented.

Between 1950 and 1970, the first and third quartiles of the white distribution changed very little, but among nonwhites the first and third quartiles rose. Particularly sharp jumps at the first quartile point occurred in the 1960s as nonwhites moved out of low prestige jobs as farm laborers or factory workers. As a result, the occupational distributions of white and nonwhite men became increasingly alike (Hauser and Featherman, 1974a:259-61). The dissimilarity index for men fell from 43 in 1940 (not shown) to 37 in 1960 (see Figure 4) to 31 at the end of that decade and to 26 in 1975. The relative improvements in the occupational status of nonwhite women were even greater than those for nonwhite men. In 1940, three-quarters of employed black women worked as domestic servants or as farm laborers (Bancroft, 1958:86). This

U.S., Bureau of the Census, Census of Population: 1950, P-C1, Table 128: Current Population Reports, Series P-57, No. 190, Table 16. U.S., Bureau of Labor Statistics, Employment and Earnings: Vol. 6 through 22, Occupational Distribution by Sex and Color, Annual Average.

Figure 4. First and Third Quartiles of Occupational Prestige and Indexes of Occupational Dissimilarity, 1950 to 1976

changed as black women moved into service jobs, clerical and sales positions. By 1975, only 10 percent worked as domestic servants or on farms (U.S. Bureau of Labor Statistics, 1976: Table 19).

The occupations of nonwhite workers were upgraded during the 1960s and 1970s. We examined annual changes in the numbers of whites and nonwhites employed in each of the major occupational categories and found that the number of nonwhites working at non-manual jobs or as craftsmen grew much more rapidly than the number of white workers in those occupations. Presumably, barriers to black employment in these prestigious jobs fell during the 1960s and 1970s. (For a discussion of crafts occupations, see Snyder and Hudis, 1976:230-1.) Two of the white-collar occupations—managers and sales—involve supervising other employees or meeting the public as a representative of the employer—jobs which were once reserved to whites. Gains in nonwhite employment in these classifications during the 1970s appear to exceed the gains of the 1960s (Garfinkle, 1975).

Throughout the period after the Depression, the occupational distribution of nonwhites improved as nonwhites moved away from jobs on farms or in domestic

service. Substantial gains were registered by blacks after 1960 and were not negated in the 1970s. Nevertheless, these changes have not eliminated the very large gap between the occupations pursued by whites and by nonwhites. Despite three and one-half decades of improvements, the average prestige score for nonwhite workers in 1975 was inferior to that of white workers in 1940 (U.S. Bureau of the Census, 1943b: Table 62; U.S. Bureau of Labor Statistics, 1976: Table 19).

FAMILY INCOME TRENDS

The most widely used statistics concerning the economic status of blacks are those showing median family incomes. The Census Bureau has tabulated such data since 1947; a summary is presented in Table 2.

Shortly after World War II, the median income of whites was approximately double that of nonwhites (see Table 2). Gains were made by blacks, especially in the late 1960s, and an income peak was reached around 1970 when black families had a median income 64 percent as great as whites (Wohlstetter and Coleman, 1972:19-29; Horowitz, 1974: Table 10-1; Thurow, 1969: Figure 2-2).

Ratios of medians offer one assessment,

Table 2. Trends in the Income of White and Black Families: 1947 to 1975

Year	Median Family Income in Constant Dollars ^a		Black Median Income as Percent of White	Index of Dissimilarity ^b
	Blacks	Whites		
1947	\$3,888	\$7,608	51%	38.3
1950	4,178	7,702	54	36.8
1955	5,113	9,271	55	34.7
1960	5,871	10,604	55	31.7
1965	6,812	12,370	55	32.8
1967	7,859	13,273	59	31.0
1968	8,292	13,826	60	29.1
1969	8,807	14,379	61	28.9
1970	8,703	14,188	61	27.3
1971	8,558	14,182	60	28.2
1972	8,831	14,858	59	28.0
1973	8,804	15,254	58	29.3
1974 ^c	8,737	14,633	60	27.8
1975	8,779	14,268	62	26.3

but a more complete view may be obtained by measuring the overlap of the two income distributions. Indexes of income dissimilarity are shown on the right in Table 2. Between 1947 and 1960 this index declined from 38 to 32, indicating a growing overlap. During the 1960s, further gains were made by nonwhites and, at the end of that decade, the income distributions of the races overlapped more than at previous dates.

Family income trends in the most recent six-year span differ greatly from those of the preceding period. Rather than growing, family income, as measured in constant dollars, stagnated in the 1970s and, in 1975, the median incomes of families of both races were slightly lower than they were in 1969. The trend toward higher ratios of black to white medians ceased and the indexes of dissimilarity which measure the overlap of the income distributions of black and white families declined more slowly in the 1970s than in the 1960s. If family income is the criterion of status, there is no evidence that the pattern of improvement which was seen in the 1960s continued into the 1970s. On the other hand, blacks have not fallen further behind whites.

Changes in Family Composition

Trends in family income are influenced by changes in living arrangements of children and parents. Since 1960, four major shifts in American family structure are evident. First, a growing proportion of marriages end in divorce. The divorce rate—as indexed by the ratio of divorces to married women—began to increase in the 1950s (Glick and Norton, 1973: Table 1) and continues to rise (U.S. National Center for Health Statistics, 1976a: Table 2; Preston, 1975). Approximately one out of five first marriages of women who reached marriagable age in the 1940s ended in divorce. If present rates persist, about one in three of the first marriages of women who reached the same ages in the 1960s will be terminated by divorce (Glick and Norton, 1973: Table 2; U.S. Bureau of the Census, 1972: Table F).

Second, an increasing proportion of women are heads of families. In 1960,

about five percent of white and 15 percent of nonwhite women ages 25 to 44 were family heads. By 1975, these proportions grew to nine percent among white women and 32 percent among black women (U.S. Bureau of the Census, 1964: Table 2; 1975c: Table 2).

Third, the percentage of births out of wedlock had risen sharply. The proportion of births which were illegitimate was two percent among whites in 1960 and 22 percent for nonwhites (U.S. National Center for Health Statistics, 1969: Table 1-24). The fertility rates of married women have fallen more rapidly than those of single women (Cutright and Galle, 1973; Glick and Mills, 1974:6) and the proportion of births illegitimate in 1974 was seven percent among whites and 47 percent among blacks (U.S. National Center for Health Statistics, 1976b: Table 11).

Finally, the proportion of children who live with both parents—real or adoptive—has declined. In 1960, 90 percent of white children under 18 and 66 percent of nonwhite children lived with both parents. Fifteen years later, these proportions fell to 85 percent for whites and 49 percent for blacks (U.S. Bureau of the Census, 1964: Tables 1, 2, 19; 1975c: Table 4).

Families headed by women traditionally have had incomes about one-half as great as families headed by men, and children in families headed by a woman are much more likely to be impoverished than children in families headed by a man (U.S. Bureau of the Census, 1963a: Table 224; 1975b: Table 2; 1976c: Table 17). If we analyzed trends in family income or welfare without controlling for changes in living arrangements, we would underestimate the improvements which may have occurred.

Table 3 indicates the income of families by type in 1959, in 1969—when black family income peaked—and in 1975. Figures are shown for total families, for families which include both spouses and for families headed by women. At each date about three percent of the nation's families were headed by a man who did not have a wife present, and data are not shown for these families. Table 3 presents

Table 3. Median Incomes (in Constant 1975 Dollars) of White and Black Families by Type and Average Rates of Change: 1959, 1969 and 1975

	Median Income			Average Annual Rate of Change	
	1959 ^a	1969	1975	1959 to 1969	1969 to 1974

^a Data for 1959 refer to whites and nonwhites.

Sources: U.S. Bureau of the Census, Census of Population: 1960, PC(1)-1D, Table 224; Current Population Reports, Series P-60, No. 75, Table 17; No. 103, Tables 1, 3 and 4.

median income by race, ratios of median incomes, annual rates of change of the medians and the racial gap in purchasing power measured by the difference in medians.

During the 1960s, black families of both types—husband-wife and female-headed—experienced greater gains in income than comparable white families. The 1969 to 1975 interval was much less prosperous than the preceding decade, and the growth rate of the median income of families was actually negative. Nevertheless, the median income of husband-wife black families rose and the rate of increase was greater than for similar white families, that is, 1.2 percent annually for husband-wife blacks versus 0.1 percent for whites. The median income of families headed by black women did not change but that of similar white families fell by 0.9 percent annually.

There appears to be a puzzle. The median income of total black families declined in this span and the racial difference in purchasing power remained essentially constant at about \$5,500. However, the median income of the most common types of black families—husband-wife and female-headed—rose or remained un-

changed and, for families of these types, the racial difference in purchasing power decreased substantially. This is explained by the shifting distributions of families by type. Female-headed families—the lowest income families—became a larger component of total black families, increasing from 28 percent in 1969 to 36 percent in 1975 while husband-wife families fell from 68 to 60 percent (U.S. Bureau of the Census, 1970b: Table 17; 1976c: Table 1). This suggests that the analysis of family income trends must take into account the changing living arrangements of children and adults.

Trends in Personal Earnings

Since changes in family composition confound trends in family income, it is important to examine the earnings of individuals. If blacks improved in economic status in the 1960s and maintained these gains into the 1970s, we would expect that the earnings of blacks would rise faster than those of whites and that blacks and whites would begin to receive similar pay for such characteristics as educational attainment and occupational achievement. In this section we analyze, first, whether

the earnings of blacks rose faster than those of whites and, second, whether blacks and whites receive similar pay for ostensibly similar characteristics.

Data describing the earnings of individuals are obtained in the decennial censuses, and tape files of the one-in-one-thousand samples of the censuses of 1960 and 1970 were used. Every March the Census Bureau's Current Population Survey gathers information about earnings from the occupants of 50,000 households. Tape files of the March survey may be used to analyze the earnings process on an annual basis. Data from the March, 1975, survey were studied in this investigation.

The earnings an individual obtains are influenced by his or her education and occupation. Additionally, wage levels traditionally have been lower in the South than elsewhere and, other things being equal, we anticipate that earnings are positively related to the number of hours worked. Finally, experience in the labor market should affect earnings independent of other factors. The model used in this paper specifies that an individual's earnings are a linear function of region of residence, education, occupation, time worked and experience.

To ascertain parameters for this model, each individual in the 1960, 1970 and 1975 samples was classified by sex and race. Each received a score for region—one for the South and zero for other regions. The education score equaled the number of school years completed. The occupational prestige scores were based upon the detailed—not the broad—occupational categories (Featherman et al., 1975; O. D. Duncan, 1961). An estimate of hours worked was derived from weeks worked in the year for which earnings were reported and the hours worked during the week prior to the census or survey. This variable is identified as Time in the tables. Experience was estimated by taking the respondent's current age, subtracting years of schooling and the constant, six. For most men, this represents years of labor force experience. For many currently employed women, however, this is an imperfect indicator of work experience since they may have been out of the labor force for long periods. Human capital may

deteriorate with age and, to represent this effect, the experience variable was squared. This is identified as Decay in the tables (see Mincer, 1974:ch. 5). Earnings, the dependent variable, refers to the year prior to the census or survey, that is, to earnings obtained in 1959, 1969 or 1974.

This analysis is restricted to black and white persons 25 to 54 who reported earnings and who indicated the number of hours they worked. Thus, it excludes the long-term unemployed, those who took their first jobs during the year of the census or survey, and those who worked in 1959, 1969 or 1974 but were not working at the time of the census or survey.

A variety of models have described racial differences in earnings and the returns to human capital (Masters, 1975:ch. 5; Hauser and Featherman, 1974b; Cherlin and Hodge, 1973; Thurow, 1969:76–83; O. D. Duncan, 1969; Siegel, 1965). Because census data are analyzed, the model presented in this paper omits several variables which may influence earnings such as intelligence (Griliches and Mason, 1973; Duncan et al., 1972:88–102), religion (Greeley, 1974:73–87; Gockel, 1969; Goldstein, 1969; Laumann, 1969: Table 4), timing of labor force experience (Mincer and Polachek, 1973) or characteristics of the family of origin (Featherman and Hauser, 1976: Table 8). If these or other relevant variables were included, they might provide additional information about racial discrimination.

Means and standard deviations of the variables are shown in Table 4. Figures in the first row reveal that the earnings of blacks have risen faster than those of whites. Between 1959 and 1969, the mean earnings of white men rose 27 percent; those of black men rose 51 percent. Among women, the increases were 24 percent for whites and 69 percent for blacks. From 1969 to 1974, the earnings of whites—in constant dollars—actually declined but blacks reported gains. Data in Table 4 refer to a select subgroup of the population. However, when all persons who reported earnings or all persons with income are considered, a similar conclusion is reached. The earnings of black men and women rose faster than those of whites during the early 1970s. On this

measure, the gains of the 1960s were not negated and the racial difference in earnings declined in the 1970s (U.S. Bureau of the Census, 1970b: Tables 45 and 54; 1976c: Tables 11 and 12).

Table 4 indicates that a decreasing fraction of blacks live in the South and that the educational attainment of black workers has risen more than that of whites. Occupational upgrading has been somewhat greater for blacks than for whites (for trends among men, see Hauser and Featherman, 1974a). Among men, there is a persistent racial difference in the number of hours worked per year. The racial difference in years of experience has been small at all dates.

Next, we considered whether the earnings blacks and whites receive, as determined by their characteristics, have changed over time. The upper panel of Table 5 shows the regression models for males and the lower panel refers to females. The first line of the upper panel indicates that, in 1959, residing in the South had the net effect of reducing a white man's earnings by \$1,002. Each year of schooling was associated with a net increase in earnings of \$676, each occupational prestige point was worth \$95 and every additional hour worked netted a white man \$1.93. The returns for an additional year of experience were \$603. These returns to characteristics are expressed in constant 1974 dollars.

The regression coefficients show that black men are paid less for their attributes than are whites. At all dates, the earnings penalty associated with living in the South was about twice as great for blacks as for whites. For both races, returns to schooling increased in the 1960s and fell back in the 1970s, but a large racial difference was maintained. In 1974, an additional year of schooling—independent of other variables—was worth about \$600 to a white but only \$200 to a black. The returns to occupational prestige have not changed greatly and, at all dates, an increment of one point on the occupational prestige scale was worth about half as much for blacks as for whites. Apparently, the racial difference in returns to hours worked has been mitigated. The earnings returns for labor force experience are

much greater for whites than for blacks and there is no indication of a diminution in the fifteen-year span covered by these data. These models suggest that black men are paid less than whites for ostensibly identical characteristics and that there have been few changes in this pattern.

Among women, there have been alterations in the rates of return and the earnings of black women are approaching those of white women. In 1959, black women benefited considerably less than white women for each year of education, but the difference attenuated and there is now almost no racial difference in returns to education among women. By 1974, the increment in earnings associated with occupational prestige was also similar for whites and blacks. The racial difference in returns for hours worked also has diminished.

For white women, the earnings returns associated with experience, as measured in this paper, were essentially nil. That is, each of the regression coefficients was smaller than its standard error. Among black women, earnings were related to experience and, over time, the returns for experience increased sharply. Black women have a different pattern of labor force participation by age than white women, and it may be that black women typically have greater on-the-job seniority than do white women of comparable age (Mincer and Polachek, 1973: Table 2; Sweet, 1973: Table 1-9; Bancroft, 1958: Table 18). This may account for the advantages black women obtain on this determinant of earnings.

The figures in Table 4 reveal that blacks earn less than whites. One reason is that blacks have different characteristics than whites. For example, more blacks than whites live in the South where wages are low. Blacks also complete fewer years of schooling than whites and work at less prestigious jobs. Another reason is that blacks generally are paid less for a given characteristic than are whites. From both analytic and policy viewpoints, we would like to know whether the racial differences in earnings result primarily from racial differences in characteristics or from racial differences in the earnings returns

calculated

which are associated with the characteristics we have considered.

The racial difference in earnings may be decomposed in many different fashions

(Althausen and Wigler, 1972:106-18). One method is illustrated in Table 6. In the equation which regressed the earnings of blacks upon the characteristics of blacks,

it was assumed that blacks had the average characteristics of whites rather than their own characteristics. What effect this change would have upon the average earnings of blacks was ascertained. In 1959, if black men had the regional distribution of whites but retained their own returns for region, their average earnings would have been \$650 greater. If they had the educational attainment of whites but retained their own rates of return, their average earnings would have risen \$542. This decomposition method differs from that used by several other investigators (Hauser and Featherman, 1974b:329; O. D. Duncan, 1969:97-103; Siegel, 1965).

Racial differences in characteristics do not account for the entire racial difference in earnings. There is a residual, reflecting the difference in the returns blacks and whites receive for their characteristics. In Table 6, this is labeled "the difference not associated with the independent variables." This component has been labeled the "cost of being a Negro" (Siegel, 1965) or the "cost of discrimination" (Hauser and Featherman, 1974b:329; O. D. Duncan, 1969:100). We note that this decomposition is not unique, and that different models of the earnings process might give different estimates of discrimination.

The top rows of Table 6 indicate that the racial difference in the earnings of men changed very little during the 1960s but decreased by about \$1,000 in the early 1970s. At each date, racial differences in characteristics accounted for a substantial fraction of the difference in earnings. If black men had the characteristics of whites in 1959 and 1969, they would have earned an average of \$2,500 more and, in 1974, an additional \$2,000. Nevertheless, this did not account for the entire racial difference. A black man with the average characteristics of a white man and paid at the return rates blacks received for their characteristics would have earned much less than the typical white man because of racial differences in pay rates. In 1959 and 1969, this difference, which reflects discrimination, was \$2,800 and, in 1974, \$2,300. At each date, about 53 percent of the racial difference in earnings was attributable to discrimination as estimated by this model.

Table 6 provides similar data for women. The racial difference in earnings declined from \$1,800 in 1959 to \$100 in 1974. The decomposition reveals that, in 1959, racial differences in characteristics did not account for all the difference in earnings. However, by 1959, a black woman

who had the average characteristics of a white woman and was paid at the return rates of blacks would have earned more than the typical white woman. By 1974, this advantage for black women increased to \$760. This does not necessarily indicate that employers prefer black women and are paying them more than comparable white women. Rather, as the coefficients in Table 5 show, the returns to experience are considerably greater for black than for white women.

CONCLUSION

During the prosperous 1960s, racial differences in education, occupation and income generally declined. We investigated whether this trend continued into the 1970s and concluded that the gains of the 1960s apparently were not solely attributable to the prosperity of that decade, since racial differences in status narrowed in the 1970s as they did in the previous decade. Blacks and whites, especially the young, are more alike in years of school completed than ever before. Racial differences in the occupations of employed workers continue to decline. The income gap separating black and white families has remained constant, but this is largely a consequence of the sharp rise of female-headed families among blacks. Indexes describing the income of specific types of families or the earnings of individuals generally reveal that racial differences moderated during the early years of the 1970s.

In some areas, the gains are impressive. Black women, for instance, obtain earnings comparable to those of white women with similar characteristics. However, not all indicators show improvement. Employment opportunities are apparently severely limited for many black men. The very high rates of unemployment and nonparticipation in the labor force suggest that numerous young blacks experience great difficulty in launching careers.

The four processes delineated at the outset—the urbanization of blacks, the growing demand by blacks for civil rights, more liberal court rulings and laws, and reductions in the prejudicial attitudes of whites—have provided blacks with

greater opportunities to compete for economic rewards. The occupational upgrading of blacks and their growing representation in politics (U.S. Bureau of the Census, 1975a: Table 99) imply that they are more represented in American decision making than they were at the start of World War II. These changes mean that, even during a pervasive recession, blacks did not lose the gains they previously experienced.

On the other hand, reductions in inequality are small when compared to the remaining racial differences on many indicators. A continuation of the trends of the 1960s and 1970s offers no hope that racial differences will be eliminated soon. For instance, a higher proportion of white men in 1940 than black men in 1976 held white-collar jobs (U.S. Bureau of the Census, 1943a: Table 64; U.S. Bureau of Labor Statistics, 1976: Table A-21). The purchasing power of the typical black family in 1974 was equivalent to that of a white family twenty years earlier (Table 3), and the earnings of black men lag far behind those of white men (Table 4).

LEGITIMATING MYTHS AND EDUCATIONAL ORGANIZATION: THE RELATIONSHIP BETWEEN ORGANIZATIONAL IDEOLOGY AND FORMAL STRUCTURE*

DAVID H. KAMENS

Northern Illinois University

American Sociological Review 1977, Vol. 42 (April):208-219

The purpose of this paper is to investigate the relationship between ideology and formal organizational structure in American higher education. To do so, we develop an argument predicated on the idea that colleges and universities affect individuals and the society by: (1) creating membership categories, e.g., "college graduate"; (2) legitimating the social rights and meanings attached to these groups; (3) ritually certifying individuals as members. These processes occur independently of any impact schools have on students. As a result, colleges must create and validate myths concerning the intrinsic qualities graduates possess that derive from the college experience. Organizational structures dramatize the symbolic redefinition of students and legitimate the idea that important changes actually have occurred during college attendance. The effects of given organizational arrangements are established by accepted educational theories and conventional wisdom. It is argued that organizational structure must conform to schools' self-presentation and their advertised effects on students. Schools whose structure and ideology do not match may be under pressure to change or suffer the fate of nonconformity. On the basis of these ideas, we develop a typology of symbolic definitions colleges construct about graduates and discuss how particular organizational features are used to legitimate different conceptions of "student." Data from comparative organizational studies are used to illustrate these arguments and to indicate substantive conditions that limit the applicability of this argument.

Conventional thinking and research on schools has focused almost entirely on the

effects of organizational arrangements on student attitudes and behavior. This emphasis is misdirected for several reasons: (1) because most research has shown that school organization has rather small socialization effects on students' attitudes, abilities and status choices, etc.

* I am much indebted to the following people for advice and intellectual support: Charles Bidwell, Peter Blau, Bill Bowers, John Meyer, John Michael and the anonymous journal readers.

(see for example, Feldman and Newcomb, 1969) and (2) because schools affect graduates through several other processes which have been largely overlooked due to the exclusive attention given to locating socialization effects of different organizational conditions. Schools affect individuals and society in the following ways, independently of any impacts they have on individuals. First, they are used to construct categories of membership in society to which important job and other rights and social meanings are attached (see Meyer, 1970b; Ramirez, 1973). Second, schools legitimate these rights by institutionalizing ideas about the qualities and abilities of graduates versus nongraduates. Third, schools are the agencies that ritually certify graduates as members of social status groups to whose privileges they are entitled (see Collins, 1971). All of these processes operate independently of any direct socialization effects schools have on students.

Using these ideas first proposed by Meyer (1970b), we explore their implications for a theory of educational organization and develop a set of propositions to explain the organizational diversity in American higher education. Our argument rests on two ideas about schools and school organization: (1) a major effect of schools and colleges is to symbolically redefine graduates as possessing special qualities and skills gained through attendance. This redefinition occurs independently of whether or not any actual changes in competency, etc. have occurred. (2) The legitimacy of this status transformation must be negotiated with important audiences in society, e.g., employers, and this necessitates the development of legitimating myths about the quality of students' educational experience. These ideas are validated by the social organization of schools. Organizational structure is, therefore, important in legitimating the idea that initiatives have been changed in specified directions by the school experience, independent of any actual changes. Since graduates have to be accepted as changed persons *by definition*, the symbolic construction of credible rituals of status change is of paramount importance (see Garfinkle, 1956).

Schools, especially in higher education, differ with respect to the symbolic conceptions of graduates that they attempt to institutionalize among clients. This is a major source of organizational diversity and change. In this view, organizational structure and conceptions of "student" that schools try to maintain among their publics are causally related features of their social organization. It appears that the causal relationship between these features of organization is reciprocal: changes in conceptions of "student" will produce changes in organizational structure and, similarly, externally induced changes in organizational structure will necessitate a shift in organizational self images.

Colleges, for example, that claim to be developing specialized occupational skills among their students must have a highly differentiated curriculum to point to as evidence of their ability to transmit vocationally relevant skills. Ordinarily, such programs will be accepted by employers and others as adequate verification that graduates actually have learned vocational skills.

Similarly, schools that develop such ideas about their function and their students will be under social pressure to develop curriculum structures and other features that validate these conceptions of "student." On the other hand, structural changes, such as a decline in recruitment selectivity or an increase in size, will create pressures for the adoption of new organizational ideologies concerning the *social meaning* of university attendance.

In this paper, we will emphasize the effects of symbolic structure on social organization, realizing that this relationship is nonrecursive.

Types of Myths

It is important now to consider the kinds of legitimating myths colleges attempt to construct. To do this, we draw together two different theoretical traditions: (1) the work of Turner (1961), Collins (1971) and Neo-Marxist writers on the role of education in elite formation (see Bowles, 1972; Gintis, 1971) and (2) the largely anthropological tradition of work

on rituals and initiation ceremonies that emphasizes the dramaturgical function of rites in "creating" membership in *corporate* (descent) groups (cf. Cohen, 1964; Young, 1964; Ramirez, 1973). These lines of argument lead to the development of a typology of legitimating myths that colleges attempt to institutionalize among their constituencies.

Writers who focus on the function of schooling in maintaining and legitimating the distribution of power and privilege tend to see the major distinction between schools and colleges as that between elite and mass-producing institutions. In higher education, the difference is between those colleges which are educating societal elites and those that are turning out the large, highly differentiated middle-class segment of the population. It is important to note that these arguments are not all of a piece or in agreement with one another. What is common to them is the focus on the stratification function of schooling as primary. The first dimension of our typology concerns the membership descriptions of graduates that colleges attempt to construct *vis à vis* the wider societal occupational order. The distinction here is between schools who define their students as societal elites and those who do *not* describe them as elites.

The anthropological tradition has emphasized a function of primitive rituals and initiation ceremonies assumed by modern educational systems. Rites of passage serve to induct people into membership status in society and, in the process of creating members by symbolically redefining them, they also reaffirm the social reality of society and its central values. This Durkheimian theme is central to the argument we develop, for it emphasizes that the major significance of rituals is to dramatize and validate the assumption of membership in a corporate group. What the initiates learn or feel during, and as a result of their ritual experience is of secondary importance.

Recently, anthropologists have expanded on this theme and argued that extensive rituals of puberty only occur in societies where highly developed corporate groups exist. Cohen (1964) shows that initiation ceremonies in primitive societies

occur where corporate descent groups are present. Young (1964) shows that the intensity of initiation rituals among societies depends on the degree of male solidarity. Where it is high, the acquisition of sex roles involves greater dramatization, i.e., rituals involve more people, are more elaborate and last longer.

In modern societies, schools perform this initiation function. What then are the corporate groups into which schools initiate members? According to Swanson (1971), the corporate existence of a collectivity is found in (a) its legitimated sphere of jurisdiction and (b) its legitimated procedures for collective action. Collectivities that have rights and interests of their own, independent of the purposes of their members, enjoy a greater scope of legitimate action. Furthermore, collectivities that have created an agency with the right and power to act on behalf of the whole, articulating its purposes and defending its interests, are more likely to undertake collective action.¹ Educational institutions are a major vehicle of representation and defense for corporate groups.

As this discussion indicates, collectivities can be ordered in terms of their "corporateness" within and across societies. In modern societies, the major competing units are: nation-states, attempting to mobilize their societies for economic development; traditional religious bodies; and regionally based ethnic-racial groups. In American society, the national state has been relatively weak as a corporate unit (see Huntington, 1968: 93-139; Burnham, 1970: 175-93). It has acted mainly as a device to aggregate and represent the interest of a broad spectrum of groups, rather than as a mobilizing agent in its own right. One consequence of this is that direct control of education has been left in the hands of local bodies, e.g., counties, states and private groups. Compared to other societies, national efforts to politically construct the educational system to turn out the "New American Man" and to recruit national political elites have

¹ The discussion of corporateness relies heavily on the work of Meyer and his associates (see especially, Meyer et al., 1973; Ramirez and Weiss, 1975).

Allocation to Membership in Corporate Group	Social Status in Wider Society	
	Elite	Non-Elite
Yes	1. Myth of leadership selection by achievement and value socialization	3. Myth of value socialization and skill transmission
No	2. Myth of performance-based leadership elite	4. Myth of skill transmission

Figure 1. Typology of Status-Allocation Myths Constructed by Colleges

been weak (Ramirez, 1973). For example, the U.S. has no national university to select and train high-level civil servants, though there have been many proposals to establish one (see Tyack, 1966).

While the state as a corporate unit in American society has been weak, religious bodies and regional ethnic groups have been relatively strong sources of corporate solidarity (see Greeley, 1972). Private schools have been major vehicles for articulating the interest of such groups. The diversity of American education rests on the strength of these primordial status groups (see Jencks and Riesman, 1969; Astin and Lee, 1972). While the professoriate may be rationalizing the internal culture of these institutions in similar directions, the point remains that these institutions represent the interest of special groups and are involved in conferring group membership status on new generations.

The second dimension of our typology then concerns the function of colleges as agents of corporate groups and the claims they must make about the socialization graduates have received which makes them bona fide members of such groups.

The typology has two dimensions, based on the functions colleges claim to be performing: (1) as elite selection and training institutions and (2) as agents of corporate groups. To illustrate: private institutions often claim to be performing both functions. Public institutions are divided between those claiming elite training functions and those involved in middle-class occupational certification. The typology is presented in Figure 1.

These two dimensions of status allocation involve two separate kinds of claims colleges must make about their graduates:

(1) the level and quality of intellectual selection and training they have received and (2) the intensity and kind of value socialization students have undergone. Our purpose is to argue that organizational structures serve as *indices* of each of these socialization processes and thus operate to construct and validate social descriptions of graduates. Organizational development reflects the particular historical balance between these claims at which given institutions attempt to arrive. The dominant movement in American higher education has been for schools to de-emphasize their role as agencies of elite formation and as agents of primordial status groups. This is due partly to the economic costs of appropriate organizational arrangements and to the rationalization of academic culture.

For convenience, let us discuss these ideas one at a time, realizing that, in fact, institutions may have to legitimate several sets of descriptions of graduates simultaneously.²

² We need to emphasize the independence of legitimating myths from the actual "contextual" effects schools have on students. The research on higher education is consistent in the fact that differential selection accounts for most of the effects of colleges in affecting students' status allocation, though there are small and interesting aggregate college effects (see Feldman and Newcomb, 1969; Astin and Panos, 1969; Meyer, 1970a; Farkas, 1974). Furthermore, college effects on students' attitudes and values also appear to be very limited. Empirically, very little diffuse socialization appears to occur directly as the result of college structure (see Meyer, 1970b; for other views, see Parsons and Platt, 1970; Dreeben, 1968). Unlike Bidwell and Vreeland (1963), who introduced the distinction between "moral and technical socialization," our focus is on definitions of graduates which colleges develop and *not* on the "contextual effects" their organization produces.

Value socialization. Colleges that define themselves as agents of corporate groups must maintain a commitment to diffuse socialization so that graduates are seen as more committed to group values and traditions than when they entered college. Examples of such schools are: ethnic or racial institutions, private sectarian colleges, military academies and, perhaps, colleges attempting to create an intellectual elite (see Clark, 1971). In addition, if they define their mission as that of providing leadership elites for such groups, these colleges must create special rituals that separate potential leaders from non-leaders and give the former special training and status within the school. To do this, colleges must develop screening mechanisms and other organizational arrangements to inform audiences that group values are being effectively transmitted.

Competence selection and training. All schools must make some claims about the competencies of graduates. Colleges training societal elites must, however, symbolize different kinds of preparation. They must sustain the idea that graduates have been rigorously selected and have received intensive intellectual training and opportunities to develop analytical skills and leadership qualities. High status private and public institutions are examples of this type. Elite technological institutions also probably fit this category. Control over recruitment, high internal standards and other arrangements that reflect these ideas are essential symbolic devices for these schools.

Lower status colleges must also construct competency myths about graduates and maintain them. These ideas center around occupational skill training that graduates receive. Public colleges, less prestigious state universities and poor private institutions are examples of these schools. This is the largest group of colleges. Such institutions must sustain the idea that graduates possess a variety of technical skills which are available *only* to those who attend college. These conceptions of graduates are effectively symbolized by a highly differentiated curriculum and degree structure and other

certification rituals, e.g., internships, practicums and specialized facilities.

As the typology indicates, some colleges must construct complex sets of descriptions of graduates via their organizational arrangements. This produces problems of balancing and integrating sometimes competing definitions and of maintaining organizational audiences.

Legitimizing Myths and Ritual Structures

Our task now is to describe briefly the organizational structures which colleges develop to support their definitions of graduates and to provide an interpretation of the dramaturgic functions of specific organizational arrangements. The list of organizational features below is incomplete, but it provides a useful starting point for this analysis.

A. Selectivity. This is a major legitimating strategy for colleges who are trying to define their graduates as elites. Selection rituals can either be established at the point of entry to the school, thus creating the myth that admission to the school itself confers elite status (Turner, 1961) or they can be developed as internal features of the organization (Dornbusch, 1955). Public universities, for example, often have negotiated stringent selection rules about who will be admitted with their major client, the state. Prestigious private colleges can control selection directly through admissions policy.

Where such direct control is weaker, colleges often resort to developing internal selection processes that establish their reputation as highly competitive, meritocratic institutions. Flunking out large numbers of students and creating the myth of the freshman year are examples of the devices used to establish this idea among clients.

Schools that define their graduates as special leadership elites may develop selection rituals both at the point of entry and during the early part of the school career. The national military academies, for example, use such strategies since they have to establish that their graduates have both intellectual skills and special group-relevant leadership qualities. Inter-

nal selection symbolically guarantees audiences that the school has devices for separating those with leadership qualities from non-leaders, even though most students successfully pass this internal screening.

B. Residentiality and "collegiate" residential structure. This variable has figured prominently in the theoretical literature (e.g., Newcomb, 1943; 1962) and in debates among educational policy makers (see Brothers and Hatch, 1972, for a summary of the British policy debates). Though there is *no* consistent evidence to support the claim, a great deal of importance has been attached to residential structure in American educational theory (see Feldman and Newcomb, 1969; Brothers and Hatch, 1972, for a summary of the evidence). This emphasis on the direct socialization consequences of residential structure overlooks its important dramaturgic effects on the audiences of schools. Colleges that are the moral agents of corporate groups must indicate that their members have undergone intense socialization experiences and have been personally transformed into effective value carriers and agents of the group. Residential structure serves this definitional function and legitimates such conceptions of graduates. First, it establishes symbolically the transfer of socialization authority from parents to the school and thus locates the school by *definition* as possessing authority over students. This transfer of authority has historically been given legal status in the now discredited doctrine of "in loco parentis." Second, it establishes the credibility of the claim that intense socialization is actually occurring and is under the control of the school. The vesting of schools with broad moral and legal authority and the existence of a control structure, i.e., residential arrangements, confirm by definition the school's ability to affect students' values and character.

Residential structures symbolically validate the authority of colleges in another way. They *remove* students physically and socially from membership and participation in other groups and thus reaffirm the identity-conferring ability of the

college. This point has been given much attention in the socialization literature, and it is worth emphasizing *if the symbolic features* of this process are attended (see Scott, 1965). Removing candidates from "everyday life" is often an important way of calling attention to their distinctive status, apart from whether such isolation per se among peers actually has any socializing effect on recruits. In practice, it is, of course, usually empirically impossible to separate the effects created by the isolation, etc. from those created by the special status definitions such a ritual confers on them.

Residential structures vary in a number of ways that should be considered separately, though these items may approximate a scale. The dimensions are: (1) the presence of *rules* of residence requiring collegiate residence of all or most students; (2) rules specifying the responsibility of faculty for non-academic residential life; (3) the actual structure of control, e.g., faculty-student ratios *within* residential units; (4) the actual proportion of the student body living in collegiate residential units. These aspects of residential structure, we suggest, symbolize different *degrees of intensity of socialization rituals*.

This discussion of residential structure is limited to a specific historical context: twentieth-century American higher education. Historical analysis of the evolution of residential structures and educational "theories" vividly illustrates the dynamic nature of the relationship between ideology and formal structure of organizations. Residential colleges began as hostels for poor scholars in the thirteenth and fourteenth centuries (see Arries, 1962:155 ff.). Attracted by the discipline of these hostels, wealthy families began to seek admission for their children. As the social composition of the student group changed, residential "colleges" underwent a change in structure and ideology: the vocabularies of discipline were invoked to justify the entry of wealthy scholars and, in turn, the change in student social composition produced new myths about the colleges and their products.

C. College size and complexity. They refer to a central feature of bureaucracy—the degree of role specialization and structural differentiation. Complexity refers directly to the latter property, i.e., the number of functions that are incorporated in the college structure. Size/complexity functions to define for audiences the symbolic primacy and effectiveness of undergraduate socialization. First, they are likely to be seen by audiences as indicators of the *extent* of direct organizational control exercised over students by faculty and other official agents of the school. Small schools with no graduate programs, for example, are likely to be defined as involving students in direct and intense relationships with faculty, administrators, etc., regardless of whether they actually do and, hence, of having important socialization effects. Second, size is also apt to be viewed as indicating whether the school represents a community of value and, hence, is capable of moral socialization.

Size and complexity signify to audiences the intensity of socialization students undergo and ritually justify the assumption that important changes have occurred during college, e.g., increases in maturity. Schools involved in defining their graduates as corporate elites and in maintaining group membership boundaries must develop organizational legitimating strategies involving size. Several alternatives are possible. Colleges can remain small and simple in structure but pay the price of offering fewer programs and being unable to attract highly qualified faculty and students. Or they can develop graduate schools, etc., but maintain the distinct identity of the college by some form of structural separation of it from the graduate divisions. The third option is to develop smaller, decentralized college units within the context of a large, complex university. All three represent adaptations that colleges can choose to solve the problem of symbolizing their effectiveness as agents of value socialization and as agencies involved in competence-based selection and training.

Colleges without the responsibilities of maintaining status boundaries may, on the other hand, find that they must promote

internal structural differentiation in order to affirm that they are capable of equipping graduates with the depth and diversity of competencies needed for either elite or non-elite occupational status.

D. Formal curriculum. This characteristic plays a central dramaturgic function, since it directly symbolizes the purposes of the college and the meanings attached to the undergraduate experience. It also indicates to audiences the intrinsic qualities which graduates have assimilated. Both the content of the curriculum (its diversity) and the technology of instruction (tutorials, work study) are used to legitimate the symbolic redefinition of graduates (see Clark, 1971). Colleges that allocate students to membership in corporate groups will attempt to expose *all* students to similar formal socialization that emphasizes group values and traditions and that is *defined* as developing moral character or leadership abilities as well as technical skills. This may involve sectarian religious education or exposure to subjects that are defined as embodying group values, e.g., black studies, military history.

Schools preparing students for elite status in the wider society are apt to maintain a commitment to providing a broad, common education for all, e.g., general education programs, together with specialized training in diverse substantive areas. Both are important in defining students as societal elites. Liberal arts training is currently accepted as the best way to select and develop general intellectual excellence, and substantive specialization is defined as developing high level analytical skills and knowledge. Colleges that emphasize the transmission of skills and define their graduates as specialists must opt for wide diversity of programs and training technologies. A highly differentiated vocational curriculum is for them an important symbolic device in establishing that they actually transmit substantive competencies and occupationally relevant skills to students. This definition of graduates and congruent organizational self-presentation produces a continuing built-in pressure for organizational differentiation. The curriculum, in this view, is a major vehicle for the *imputation* of

motives and social identities to candidates. It is important because of its agreed-upon identity conferring properties and, once established as a central feature of college structure, such "technologies" become central elements of organizational myth and thus resistant to change. Change comes when *organizational* conceptions of "student" shift, or when externally induced changes in structure occur.

E. Demographic structure and geographical location. Moral socialization is often viewed as requiring the isolation of initiates from potential sources of disruption and corruption. In American educational thought, two influences have been seen as such, though the trend is rapidly changing: cities and the opposite sex. The former have been seen as cultural competitors to college and, hence, capable of undermining its socializing influence. Thus, until recently there has been a strong anti-urban strain in American social and educational thought.

Similarly, single-sex education also was supported as aiding the college's socializing capability. It did this in two ways: (1) this arrangement made available to the college a great deal of sublimated erotic energy and, hence, increased its control and (2) it prevented the withdrawal of students from the public life of the college into private heterosexual relationships, thus removing them socially and psychologically from the control of their peers and the college (see Newcomb, 1943). Hence, the demographic structure was viewed as another way of intensifying the college *experience* and the moral authority of the organization through the increased peer and organizational solidarity it produced.

Organizational Myths and Structure: A Set of Propositions

The main propositions of our argument are:

- A. Schools constructing elite-forming claims will dramatize their *selectivity*, whether or not they are actually very selective in recruitment. They may also organize *internal* selection rituals and dramatize them, e.g.,

academic "mortification" processes.

- (1) In addition they must also dramatize their ability to give intensive, high level intellectual training. This leads them to organize the following features: high teacher-student ratios and a highly qualified teaching staff.
- (2) Schools making elite-developing claims must remain small because size is an important way of dramatizing selectivity.
- (3) Similarly, schools making elitist claims must restrain the differentiation of faculty and programs around "specialties."

B. Schools producing occupational specialists or "college graduates" will organize and dramatize certification rituals that are bureaucratically organized and administered. These include:

- (1) a complex degree structure
- (2) a diverse and vocationally oriented curriculum
- (3) bureaucratically organized competency requirements, e.g., courses, tests, internships, time in residence, etc.

C. Schools producing entry into corporate groups will organize residential structures and other boundaries between the school and society and will dramatize such features.

These propositions should be seen as dynamic and nonrecursive, though we have framed them to emphasize the effects of ideology on formal structure. The order of causality could just as easily have been reversed. Pressures for change may come from either structural or ideological shifts.

Dynamics of Organizational Growth and Change

This argument about the symbolic functions of organizational structure indicates that schools adopt specific features not for reasons of internal functional efficiency, but because the *costs in terms of*

external legitimacy of not adopting them are prohibitive. Organizations develop and change in response to the prevalent functional theory of organizational structure in their environments (see Meyer, 1975; Blau, 1973:258ff.). While we have emphasized the cost in legitimacy to an organization of adopting formal structures that are defined as inappropriate to its proclaimed functions, i.e., socialization outcomes, schools also can incur such costs in another way. They can adopt or maintain ideologies about graduates that are incompatible with changes in structure that have occurred. Schools can become victims of their own mythology in periods of rapid social change.

For educational organizations, the symbolic function of their structures creates special dilemmas. Competency claims and value socialization claims may dictate the choice of very different kinds of structures as legitimating devices. For example, colleges that seek to define their graduates as societal elites must attract highly able students and faculty. Both, however, are attracted to large institutions that are both affluent and highly differentiated. The best faculty want and need colleagues working in their specialty, and able students are lured by the presence of an eminent research-oriented faculty and a rich diversity of departments and programs (see Blau, 1974). Similarly, schools attempting to maintain corporate status boundaries also must be able to certify students as possessing special skills. Such certification, however, increasingly requires a highly differentiated curriculum. Yet these pressures for differentiation and growth threaten to sacrifice irreversibly some of those very structural features discussed earlier by which colleges legitimize their ability to affect intensive intellectual training or diffuse value socialization. Historically, the issue for many schools has been the choice between growth and expansion of organizational functions or maintenance of ritual structures appropriate to maintaining group status boundaries or for elite development. Advocates of expansion and academic quality frequently have won these battles and thus many schools have

given up conceptions of graduates as societal elites or as members of corporate groups.

This argument about the relationship between the conceptions of students that schools construct and their social structure suggests two general propositions about rates and levels of growth and differentiation: (1) *rates* of growth will be lower for universities and colleges which define themselves as elite training institutions or as the value socialization agencies of corporate status groups and (2) the absolute *levels* of size and structural differentiation will be lower for such institutions *when* the level of institutional resources and other indicators of academic quality, e.g., faculty prestige, are controlled. Given the nonrecursive structure of the relationship between ideology and formal structure, we also expect that schools that opt for high growth rates or that experience high levels of differentiation will drop elitist claims and ideas about diffuse socialization in favor of new ideologies about their function and effects on students.

Two recent research findings help to illustrate this argument. While the first is readily susceptible to alternative interpretations, the latter is more puzzling and less easily explained. In a survey of college administrators, Sieber et al. (1968:18-9) found that among officials at *private* universities the greatest amount of ambivalence or mixed feelings occurred concerning goals pertaining to *organizational expansion*. As Sieber et al. (1968:18-9) observe, "the issues seem to be whether private universities should share the functions of other types of institutions of higher education. . . ." Public university administrators were *not* as likely to have mixed feelings about expansion but were more ambivalent about the goals of developing a national leadership cadre, developing moral capacities and ethical standards, and several other service goals (Sieber et al., 1968:18). Private universities were also found to exceed all other institutions in emphasizing the organizational goal of "developing a leadership cadre to serve the nation and the world" (Sieber et al., 1968:21). This evi-

dence suggests the negative relationship between the *goals* of elite formation and organizational expansion.

A second set of findings shows that established institutions are less differentiated than others. In a study of American colleges and universities, Blau (1973:256) found that *older* universities were likely to attract better students, to pay better salaries and thus recruit more qualified faculty *but* were also *less* likely to create new departments, i.e., were less structurally differentiated. He interprets this resistance to innovation as the result of academic conservatism engendered by a long tradition of scholarly leadership. An alternative interpretation suggests that organization *age* is associated with elite training goals. According to proposition two, older universities should also be smaller and less complex when the level of institutional resources is held constant (see Huntington, 1968:13ff. for a discussion of the meaning and correlates of organizational age). Substantively, organizational age may indicate the ability of schools to claim a role in the development of national leadership elites. Older universities are more likely to be intensely committed normatively to corporate value socialization and goals of elite formation, since they are associated with charter ethnic groups that have had a longstanding role in national leadership. Such colleges have developed a tradition of producing leaders of government, business and the professions, notably high finance and corporate law (see Collins, 1971); and this "saga" becomes a central definition of the rights and meanings attached to graduates. According to our argument, these symbolic conceptions of graduates should lead them to dramatize selectivity by resisting increases in size and to dramatize broad intellectual preparation of students by resisting academic specialization until such work can be integrated into the undergraduate curriculum.

The major objection to this general argument is substantive and will serve as an important qualification. In many societies, the organizational structure of schools is not an important source of legitimation of symbolic definitions of

graduates because the latter are institutionalized *in society*. In the Philippines, for example, the meaning and functions of the national high school in Manila are established by the fact that its graduates are *defined* as important political actors and as prospective political elites by virtue of their *admission*. The prestige and meaning of "student" derive from the school's chartered role as an agent of the state. Organizational structure plays little role in this process (Meyer, 1970b). One empirical consequence of the institutionalized definitions of the school and its graduates is that students who pass the series of national exams for admission experience dramatic changes in self esteem *before* they even reach the school (Benitez, 1973).

Such schools have to dramatize their selectivity, but this is done by *societal* arrangements, e.g., nationally-administered entrance tests, and not by organizational features. Also, such schools do not need to dramatize the separation of school from society by the construction of residential features and other symbolic structures. Value socialization is validated by the institutionalized societal definitions of the school and its graduates. Hence, the legitimating function of school organization is constrained by societal definitions of education and of schools.

Conclusion

This paper has stressed the importance of the social meaning attributed to university attendance for understanding organizational structure and development.

Rather than review all of the argument, we will summarize the major idea and indicate its implications for the study of schools.

Schools symbolically redefine people and make them eligible for membership in societal categories to which specific sets of rights are assigned, e.g., income. The social organization of schools is a major symbolic index of the kind of socialization that has occurred and thus legitimates the conferral of specific status rights. Organizational characteristics are thus causally

linked to the social meanings attached to university attendance.

This argument has several research implications for the study of schools. The following kinds of research are required to develop and test this line of argument: (1) comparative studies that investigate the relationship between organizational features and the specific images schools present of themselves and their graduates; (2) research that investigates whether schools with elitist myths and appropriate organizational structures actually are more likely to produce elites than schools with only one of the two components (either myth or structure); (3) studies over time of how changes in either myth or structure trigger changes in the other; (4) studies of the fate of organizations that *resist* synchronizing their ideology and structure, either by holding on to myths long after their supporting structures have faded or by maintaining organizational structures associated with outmoded images of students. This is an area where case studies of the *process* of change and resistance would be useful.

POLITICAL WITCH HUNTS: THE SACRED AND THE SUBVERSIVE IN CROSS-NATIONAL PERSPECTIVE*

ALBERT JAMES BERGESEN
University of Arizona

American Sociological Review 1977, Vol. 42 (April):220-233

This paper proposes a general theory of political witch hunts, viewing them as ritual mechanisms for the periodic rejuvenation of collective sentiments in national societies. Ultimate national purposes require not only their worshipers, but also their enemies. When these sacred forces penetrate daily reality, then their opposites—subversives—will also appear in daily institutional life. The corporateness of societies, as expressed in their political system, is theoretically linked to the penetration of transcendent reality into daily life, and a witch-hunting dispersion index is proposed to measure the extent to which subversion is ritually discovered throughout a society's social institutions. The overall rate of witch hunting is also measured. Data on rates of political witch hunting between 1950 and 1970 for 39 countries is presented to evaluate the general theoretical argument. The data suggest that as societies politically express more of their corporate national interest they ritually cleanse more institutional areas, as measured by the dispersion index. Along with the representation of the corporate national interest, the overall rate of witch hunting is significantly affected by country size, level of economic development and the relative power of the state. The dispersion of witch hunting, on the other hand, is unaffected by these control variables and seems to be a more purely Durkheimian phenomenon.

Modern national societies, like primitive societies, must periodically renew the meaning of corporate existence. Where rites were once performed to symbolizations of the tribe, they are now performed to symbolizations of the nation-state. Durkheim (1965) observed that sacredness required profanity, and sacred national purposes seem to require those who would undermine and subvert them. Similarly, as Durkheim argued that crime is a normal aspect of social life, so are political witch hunts. The nation-state's creation of political subversives, no less than the community's manufacture of deviance, is a mechanism for renewing common moral sentiments and redefining the contours of social reality.

This theoretical perspective on political witch hunting derives from and links Durk-

heim's observations on religious ritual and myth and the social functions of crime. His work in religion and crime has a common concern with the function of ritual activity in creating and maintaining collective reality, whether symbolic representations in the analysis of primitive religion or moral boundaries in the analysis of crime. However, there has been little intellectual contact between later students of the sociology of religion (for example, Swanson, 1964; 1967; Douglas, 1966; 1970; Goffman, 1956; Berger, 1969; Luckmann, 1967) and the sociology of deviance (Erikson, 1966). Moreover, this theoretical formulation is congruous with two empirical findings which recur in studies of political trials (Cohen, 1971; Kirchheimer, 1961), purges (Brzezinski, 1956; Conquest, 1968; Dallin and Breslauer, 1970), rectification campaigns (MacFarquhar, 1960; Goldman, 1965; Solomon, 1971; Baum and Teiwes, 1968) and loyalty controversies (Bell, 1964; Lipset, 1955; Parsons, 1955). Efforts at exposing, unmasking and discovering subversives seem oriented as much toward dramatizing their presence as toward ac-

* This is a revised version of a paper read at the American Sociological Association meetings, Montreal, 1974. Janine Blair assisted with the computer work and comments from Morris Zelditch, Jr., John W. Meyer and Ronald Schoenberg have been most helpful. I especially want to thank Beverly Duncan and Otis Dudley Duncan for their suggestions and assistance on an earlier draft of this paper.

tually apprehending them; and, accordingly, the arrests, trials, confessions and other acts which comprise a modern political witch hunt seem largely ritualistic in character.

The ritual mobilization of a community searching for imaginary enemies traditionally has been viewed as largely epiphenomenal—the real causes of witch hunting are thought to lie elsewhere. The trials, purges and political terror of Communist regimes, for instance, have been seen as an outcome of the fear and paranoia generated by totalitarian states and as an “instrument of the state” used by elites to thwart potential opposition and maintain political power (Brzezinski, 1956). Similarly, the hysteria of the McCarthy period has been dismissed as the paranoid projections of social groups experiencing status stress (Bell, 1964). In contrast, I want to propose a theory of political witch hunts explicitly based on their distinctly mythical and ritualistic character.

THEORY

The Sacred and the Subversive

For Durkheim, the moral reaffirmation of collective life involved two causally interrelated notions—one, that society presents itself through a variety of symbolizations or collective representations ranging from material objects to systems of ideas; the other, that society mobilizes itself through rites performed to these symbolizations as a means of periodically renewing their presence and simultaneously renewing the larger social order they symbolically represent. Like primitive societies, modern national societies present themselves through numerous symbolizations. Some are material objects like flags, emblems and political leaders. Others are symbolic representations of the national collectivity itself—images of *the Nation* or *the People* as organic entities, or political ideologies such as Communism, Socialism, Fascism or Democracy. As in primitive societies, rites are performed to these modern collective representations of the corporate national community. Some of these rites are what

Durkheim (1965) called *positive rites* where *the Nation* and *the People* are worshipped: coronations, inaugurations, national holidays and memorial days. Others are *negative rites*, like witch hunts. Through such activities as the purge, trial, investigation, accusation, arrest and imprisonment, society creates its own internal enemies to ritually reaffirm the very sacred national purposes which subversives are supposedly undermining. The corporate nation needs not only its worshippers, but also its enemies. This process of moral revitalization is complex, centering on the interrelationship of corporate society, its collective representations and the ritual which rejuvenates and redefines them.

The Penetration of Ordinary Life by Sacred Forces

Social reality is a matter of definition. It is neither naturally mundane, with ordinary people and profane motives, nor sacred, with transcendent political purposes animating individuals and social events. Depending upon how closely a nation's collective myths are merged with the profane and ordinary, more or less ultimate political significance can be infused into daily existence. The penetration of daily life by sacred forces is, in effect, a variable, and not the singular property of primitive religious systems as we have traditionally believed.¹

In pluralistic Western societies, by and

¹ Bellah (1970:27), writing on religious evolution, argues that one of the distinguishing characteristics of primitive religion is “the very high degree to which the mythical world is related to the detailed features of the actual world. Not only is every clan and local group defined in terms of the ancestral progenitors and the mythical events of settlement, but virtually every mountain, rock, and tree is explained in terms of the actions of mythical beings.” The same could be said for the so-called modern religious situation. In certain highly ideological societies, for example, virtually every individual action is linked to the transcendent world of History or Nature and every event is seen as an instance of the mythical forces of “imperialism,” “socialism” or “capitalism.” Because our religious representations are at the same time the theory of our own universe, we have had a very difficult time assigning some beliefs to the category “myths” and others to what we take as constituting our “real” reality.

large, life is understood as the interaction of groups and personages governed by secular and profane motivations of the here and now. Life is not filled with the rumbling and movement of Marx's historically preordained struggle between social forces in "constant opposition to one another, carrying on an uninterrupted, now hidden, now open fight." Conversely, the two most pronounced examples of sacred political forces mingling with people in daily life are Fascist and Communist societies where there is a very close connection between religious representations and daily existence.

Underlying the Nazis' belief in race laws as the expression of the law of nature in man, is Darwin's idea of man as the product of a natural development which does not necessarily stop with the present species of human beings, just as under the Bolsheviks' belief in class-struggle as the expression of the law of history lies Marx's notion of society as the product of a gigantic historical movement which races according to its own law of motion to the end of historical time when it will abolish itself. (Arendt, 1973:463)

These ideologies can be considered Durkheimian representations of the corporate social order. Individuals come and go but groups persist: the idea of an unending universe of evolving Nature or History is the perfect symbolization for the corporate continuity of society over the temporary lives of mundane individuals. From the point of view of highly corporate societies, those countries in which groups and classes do not realize their participation in the transcendent reality of historical development are said to have "false consciousness." From the other side, these corporate societies are described as highly "ideological" and their people as "brainwashed." Each side claims its experience of reality to be correct and the other's false. What is experienced, though, is mediated by each society's definition of reality, and there is no absolute reality independent of society and its imposed system of classifications and definitions.

Political ideologies, like the sacred forces of History and Nature, or the ideas of *the People* or *the Nation* can penetrate and merge with ordinary reality so that

daily activity becomes the realization of these transcendent realities. The ritualistic creation of enemies, as a means of renewing the presence of these sacred forces, centers on discovering "enemies of the people," the nation, and even enemies of Nature and History itself.

Terror . . . its chief aim is to make it possible for the force of nature or of history to race freely through man . . . [it] singles out the foes of mankind against whom terror is let loose, and no free action of either opposition or sympathy can be permitted to interfere with the elimination of the "objective enemy" of History or Nature, of the class or the race. Guilt and innocence become senseless notions; "guilty" is he who stands in the way of the natural or historical process which has passed judgement over "inferior races," over individuals "unfit to live," over "dying classes and decadent peoples." Terror executes these judgements, and before its court, all concerned are subjectively innocent: the murdered because they did nothing against the system, and the murderers because they do not really murder but execute a death sentence pronounced by some higher tribunal. The rulers themselves do not claim to be just or wise, but only to execute historical or natural laws; they do not apply laws, but execute a movement in accordance with its inherent law. Terror is lawfulness, if law is the law of the movement of some suprahuman force, Nature or History. (Arendt, 1973:465)

Ritual Transformations: Trial, Purge, Accusation, Investigation

There is no clear line separating ordinary mundane reality and the larger purposes and personages of a transcendent reality such as History or Nature. One can see himself, his work and others as the embodiment of the laws of history working themselves out here on earth, as when factory work is experienced as building socialism and realizing the historical role of the proletariat. One can also find oneself engaged in mortal combat with these cosmic forces and being charged with being an enemy of socialism and conspiring against the laws of social development. In the first situation, one is marching with the sacred forces that have penetrated one's existence and, in the other, one is marching against them. In both

situations, one will probably be doing identical activities—only the definitions will have changed.

Political witch hunts are the ritual mechanisms that transform individuals, groups, organizations or cultural artifacts from things of this world into actors within a mythical universe. These rituals are the social "hooks" that keep sacred transcendent forces present in the lives of ordinary people and relevant for everyday institutional transactions. In effect, Berger's (1969) "Sacred Canopy" extends to different lengths, more or less penetrating everyday reality, with ritual being the "lock" which keeps sacred reality tied to daily reality. The discovery of "wreckers" in factories, "hostile elements" in the Party bureaucracy, "bourgeois thoughts" in literature, and "anti-state" activity in government is the ritual activity which functions to reaffirm the presence of the sacred struggle between Capitalism and Socialism within the fabric of everyday life.

The crimes one is charged with and the motives imputed are not of this world. Through some ritual transformational logic, they become part of the mythical reality of political ideology where, for example, "proletarian virtue" is battling "bourgeois selfishness" and the "socialist and capitalist lines" are struggling for supremacy. Trivial activity is ritually transformed into actions of large historical forces. Using one kind of fertilizer or another on a communal farm is transformed into the mythical world of "taking the capitalist road" or "following the socialist road." Reading a book or seeing a play is transformed into being "poisoned by bourgeois thoughts" or being a "communist sympathizer." Correspondence with friends abroad can be transformed into acts "restoring capitalism," making one an "imperialist agent" and "counterrevolutionary."

When these ritual convulsions occur, ordinary reality loses its usual meaning and human beings mingle with mythical beings, playing roles in a cosmic drama. As Hannah Arendt observed, questions of guilt and innocence are irrelevant; they are causal relations rooted in the structure of meaning of mundane reality and make

no sense when the definition of reality has been ritually shifted to the mythical world of political ideology. What one "really" did or did not do is irrelevant, for the "doing" has meaning in a world that has been supplanted by a mythical universe with its own characters, motives and crimes. Being an "ultra-leftist," "ultra-rightist," or "left in appearance but right in essence" makes no sense within the meaning structures of this world; they are acts, motives and types of people from the world of political ideology.

One does not enter this mythical world through any act one performs. The sacred and profane are two different worlds, there is nothing one can do in one world to enter into the other. Hence, guilt and innocence have never mattered during political witch hunts. The most trivial infraction, or no action at all, has the same weight as the most serious crime. It is the activity of the trial, the purge, the accusation or the self-confession which transforms individuals from one reality to the other.

It is no wonder then that witch hunts appear irrational, terrifying and *unreal*. In some sense, they are truly unreal and irrational, for their logic derives from the symbolic significance of the ritual encounters between mythical beings and forces and not from the actualities of human conduct. There is no intrinsic quality to that which is treated as sacred and there is no intrinsic quality to individuals considered subversive and dangerous. Durkheim wondered how such insignificant things as lizards, frogs, turkeys, ants and caterpillars could, in and of themselves, engender the sense of the sacred; and we have also wondered how the wording of a Girl Scout Handbook, a play exploring the thoughts of a conscientious objector, or interest in the United Nations, race relations and civil liberties could be considered dangerous, subversive and un-American. Anything can serve as a vehicle for the designation "sacred" or "subversive," and anyone can become "an enemy of the people" and "think dangerous thoughts." As Arendt (1973:462) observed:

Totalitarian lawfulness, defying legality and pretending to establish the direct reign of justice on earth, executes the law of History

or of Nature without translating it into standards of right and wrong for individual behavior. It applies the law directly to mankind without bothering with the behavior of men.

Societal Differences in Witch-Hunting Activity

Collective representations mirror the social order, and Durkheim's observation that the attitude of respect toward our gods is similar to the attitude of respect toward social authority provides the now well-known (Swanson, 1964; 1967) theoretical linkage between corporate social groups and religious experiences with sacred forces and spirits.

As mentioned earlier, the extent to which transcendent reality merges with daily reality appears to be a variable and, as these sacred forces are symbolic representations of the corporate social order, variation in the extent to which that corporateness is expressed should be reflected in variations in the extent to which the sacred cosmos penetrates mundane reality.² The more the corporate interest of the nation as a whole is politically expressed, the more sacred forces should intervene in daily life, and the more witch hunting there should be to reaffirm these collective representations and secure their presence in daily affairs. In effect, as the corporate interest of the society is weakened, so is the strength of the gods. They become less powerful, more elusive and more tenuously tied to the specifics of daily life.

For example, representations of the corporateness of the United States are not as well developed as those of Communist countries. The idea of the American People, or Public Opinion, as a force or spirit in our lives does not penetrate our existence to the extent to which representations like "the thoughts of Chairman Mao" do in China (Schwartz, 1968). Nor

are they embodied in specific political institutions to the extent to which the Communist Party is considered the literal embodiment of the "proletarian will." Finally, the American People or Public Opinion do not have a mythical link to the specifics of historical evolution as does the Communist's Proletariat. The Manifesto stated, "The history of all hitherto society is the history of class struggles. Freeman and slave, patrician and plebian, lord and serf, guildmaster and journeyman . . ." and now, in our times, the bourgeoisie and proletariat. In comparison, the "When in the course of human events . . ." beginning to the Declaration of Independence is a much more casual and almost offhand reference to the primordial origins of the American nation compared with the lockstep progression of History in the Manifesto that has brought forth present-day Socialist countries. There is also no single body of literature for the liberal democratic West comparable to that of Marxism defining, say, America's "Historical Role." There are no "sacred texts" and no common set of intellectual heroes like Marx, Lenin and Mao. Marxism provides one version of ultimate reality, which is modified to each particular social system, but is still linked to the transcendent process of social development and the laws of History.

Expressing corporateness: political party systems. Swanson (1967; 1971) argues that social collectivities have a corporate existence; they can make collective decisions and take collective action. For national societies, the structural mechanism through which collective decisions are formulated and collective action taken is the institution of government. Collectivities vary in the degree to which they allow the expression of the corporate interest of the collectivity as a whole, as opposed to the interests of the constituent groups within the society. Political party systems are the most common structural mechanism for expressing group interests, whether corporate or constituent.³

² This theoretical discussion leans heavily on the work of Swanson (1964; 1967) on corporate groups and experiences with the sacred in daily life. His ideas on immanence and constitutional systems are the backbone of my thinking about these matters, and those familiar with his work will see the strong effect he has had on my thinking.

³ The expression of corporate versus constituent interests need not always be mutually exclusive, although it most often appears that way. One exception would be a country like France which has a

Multi-party systems, such as the European parliamentary states, allow the most penetration of constituent group interests into the structure of government. Specific groups—agricultural, religious, working class—each have their own party and, with the proportional representation electoral arrangements multi-party systems usually have, these parties are virtually guaranteed some seats in the legislature. *Two-party* arrangements, like the Anglo-American countries, collapse many specific group interests into two broadly based parties. The emphasis is upon what the different groups have in common, rather than what separates them, and more of the common corporate interest of the society is manifested. Finally, there are *one-party* states, whether Communist, Fascist or one-party nationalist. Here, only the interest of the collectivity as a whole is represented by the single party. Partial interests are not provided a formal role through parties in the political organization of these nations as corporate entities.

Some Hypotheses

The penetration of sacred forces into ordinary reality is not the sole property of primitive belief systems, and the ritualistic search for enemies as a means of reaffirming these transcendent forces is not a property of any one kind of society; both vary according to the extent to which corporate, as opposed to constituent, group interests are politically expressed. We have been referring to daily affairs and everyday reality in quite general terms. We can refer to them more precisely in terms of the different institutional spheres of which daily reality is composed. We can speak of the extent to which religious, political, economic or educational institutions are found infested and polluted with subversion.

From the preceding theoretical discussion, the following hypotheses can be

made: (1) Other things being equal, there should be a positive relationship between the expression of corporate interests and the distribution of witch hunting across a society's social institutions, reflecting the more extensive penetration of daily institutional reality by sacred forces. (2) We should also expect the expression of society's corporate interest to be positively related to increased frequency of witch hunting in general. One-party states should experience subversion in more institutional areas and have a higher overall rate of witch hunting than two-party states, and they, in turn, should experience subversion in more institutional areas and have a higher overall rate than multi-party states.

DATA AND METHOD

Independent Variables

Countries were chosen for analysis if they had a stable party system from 1950 through 1970. A stable system is defined as one in which the party system did not change and the country was not involved in major political conflicts. The attempt was to isolate, as much as possible, the effect of party system upon a country's propensity for witch hunting. The countries are listed in Appendix 1. A country's party system was coded from Blondel's (1973) classification of national legislatures. Countries were coded one, two and three, representing one-, two- and multi-party systems. The 39 countries differ in population size, level of economic development and the degree to which political power is concentrated within the state, as well as with respect to political party system. The former factors may be seen as rivals to party system in accounting for cross-national differences in witch hunting and, as I am arguing that *other things being equal*, corporateness should be related to the dispersion and rate of witch hunting, I have compiled measures of each country's 1960 population (IBRD, 1973), 1960 per capita GNP (IBRD, 1973) and per capita internal security forces (Taylor and Hudson, 1971) to control for these factors.

multi-party system allowing for the expression of constituent group interests and a strong and centralized national bureaucracy which expresses the corporate interests.

Dependent Variables

Frequency of witch hunting. Counts of witch hunting activity are obtained by coding government activities (for example, trials, purges, arrests) from news sources whenever these activities charge someone with threatening or standing in opposition to the national interest. Since government represents the social structure through which the nation itself takes collective action, only acts by a country's national government will be coded (this includes the military). Charges of subversion by private citizens, for instance, will not be coded. The *New York Times Index*, 1950-1970, was chosen as the basic source because of its broad international coverage.⁴ The scheme used for coding provides for 19 different kinds of government acts, ranging from mere charges of subversive activity to large-scale purge trials. Each category is mutually exclusive. The specific code categories are: (1) warnings of danger to the nation, (2) specific charges, (3) discovery of plots, (4) calls of public action to thwart subversion, (5) proposed actions, (6) new laws, ordinances or executive decrees, (7) restrictions of personal activity, (8) expulsion of agents of foreign governments, (9) deportations, (10) arrests, (11) imprisonment, (12) resignations, (13) purges, (14) court actions, (15) mass mobilizations, (16) censorship campaigns, (17) political trials, (18) sentences following trials and (19) government investigations. This scheme is intended to cover the great variety of government activity a society can employ in creating the idea of subversion in its midst.

The coding was done by four graduate students. Activities were assigned codes independently by two coders and the value of Robinson's (1957) coefficient of

agreement was found to be .85. This compares favorably with the reliability achieved by other researchers who have coded news sources (see Gurr, 1968; Feierabend and Feierabend, 1966; Banks, 1971).

The coding scheme also provides for 36 different institutional areas in which subversion might be discovered. The information available about the activities made it impossible to determine the institutional areas for 57 percent of the government activities coded. For the present analysis, these 36 areas are grouped into seven general institutional categories: (1) government—national and local, (2) military personnel and facilities, (3) educational institutions and students, (4) economy, (5) intellectuals, (6) religious groups and institutions and (7) a category for foreigners.

The coding procedure works as follows. The *Times Index* is read for each country. When one of the code activities (a trial, purge, arrest) is encountered, it is coded along with the institutional area where the subversion was located. This procedure generates the basic data on both the overall volume of witch hunting (the number of government activities) and its institutional location. Some countries could not be coded for the full 21 years (such as the African countries, which did not become independent until around 1960), so each country's total number of activities was divided by the number of years coded, creating a witch-hunting per year variable.

The Witch-Hunting Dispersion Index. To measure the dispersion of witch-hunting activity throughout a society's institutional space, a population diversity index is employed. This 'dispersion' index, adapted from Simpson's (1949) index of population diversity, is defined as

$$D = 1 - \sum_j \frac{N_j(N_j - 1)}{N(N - 1)}$$

where N_j equals the number of witch-hunting activities in the j th institutional category, N equals the total number of witch-hunting activities and D equals the degree of dispersion of witch hunting across institutional categories. The higher the score on the index, the more dispersed

⁴ There are numerous sources of bias involved in using press reports. There are actions taken by political authorities in identifying and prosecuting subversives that never reach the pages of the *Times*. This would seem particularly true of Communist states and countries with little contact with the United States. There is also undoubtedly a bias in terms of the number of events reported for large and prestigious nations over those smaller and less known. For a discussion of some of the problems in coding news sources, see Danzger (1976).

the witch hunting across institutions. This index was computed across the categories: government, military, education, economy, intellectuals, religion, foreigners and agents of foreign governments. At least ten government activities were arbitrarily chosen as a minimum to compute an index score. No index was computed for the following countries, as they had less than ten acts within their institutional areas: Chad, Guinea, Ivory Coast, Senegal, Tanzania, Australia, New Zealand, Colombia, Belgium, Iceland and Ireland.

FINDINGS

The Dispersion of Subversion through Institutional Space and the Overall Rate of Witch Hunting

We can measure the extent to which different institutional areas are polluted with subversion using the dispersion index mentioned earlier. The higher the score the more dispersion; the lower the score the more witch hunting is concentrated within a few institutional areas. Appendix 1 presents the total number of witch-hunting activities by institutional area for each country. Control variables

for country size (population), level of economic development (GNP) and the relative power of the state (internal security forces) are entered into the following regression analysis along with the variable political party system. It was logged to help correct for the skewed distribution of the witch-hunting per year variable. The correlation matrix for the regression analysis is presented in Appendices 2 and 3.

The regression analysis in Table 1 strongly supports our first hypothesis that, other things being equal, there is a positive relationship between party system and the dispersion of witch hunting throughout a society's institutional space. The political party variable has a strong effect, with a beta of .575. It is also the only unstandardized coefficient twice its standard error. The effect of population and GNP are negligible with betas of .047 and .042, respectively, and the indicator of state power, internal security forces, has a small negative effect with a beta of -.242.

The second hypothesis stated that, other things being equal, there is a positive relationship between party system and the overall rate of witch hunting. Political party system was significantly re-

Table 1. Regression Coefficients of Witch-Hunting Dispersion Index and Log Witch Hunting per Year on Political Party System, Internal Security Forces, Population and per Capita Gross National Product

lated ($p < .05$) to the overall rate of witch hunting, but so were the control variables. All of the independent variables were significant at the .05 level and all the unstandardized coefficients were twice their standard errors. The overall rate does not seem to be a simple function of the representation of corporate or constituent interests.

One-party countries have the highest rate of witch-hunting activity. They have a median 6.1 log witch-hunting activities per year compared with only 1.6 for two-party and 1.2 for multi-party. The large score (Appendix 1) for the United States should be interpreted cautiously, as it is undoubtedly inflated by the very extensive coverage the *Times* gives the U.S. Except for Ghana, the African one-party states have very little activity. Most one-party witch hunting, therefore, was conducted by Communist countries. We have categorized countries by party system, but we have no way of further differentiating among Communist states as to the representation of partial or corporate interests within these one-party regimes. Some support for the applicability of the general theoretical argument that witch hunting is related to representing solely the collective interest at the expense of competing or partial interests is suggested by Hannah Arendt. She observes that, even for one-party Communist and Fascist states, the further elimination of competing interests is associated with an increase in witch hunting and political terror.

terror increased both in Soviet Russia and Nazi Germany in inverse ratio to the existence of internal political opposition, so that it looked as though political opposition had not been the pretext of terror . . . but the last impediment to its full fury. [In Soviet Russia] . . . full terror did not break loose in the twenties but in the thirties, when the opposition of the peasant classes was no longer an active factor in the situation.—Khrushchev, too . . . notes that "extreme repressive measures were not used" against the opposition during the fight against the Trotskyites and the Bukharinites, but that "the repression against them began" much later after they had long been defeated.

Terror by the Nazi regime reached its peak during the war, when the German nation was actually "united." Its preparation

goes back to 1936 when all organized interior resistance had vanished and Himmler proposed an expansion of the concentration camps. (Arendt, 1973:393)

To assess more systematically the importance of Communist countries per se, as opposed to the more general Durkheimian idea of corporateness, one would want to consider examining other historical forms of one-party states, developing an indicator of corporateness other than party system, or searching for a means of differentiating, among one-party states, their relative expression of corporate and constituent interests.

The Distribution of Subversion across Specific Institutional Areas

We can more closely examine the distribution of witch-hunting activity by looking at the percentage distribution of ritually discovered subversion in different institutional areas (see Table 2). The Government, Military, and Foreigners categories generally have the highest percentages of witch-hunting activity. If we exclude the Religion category, because of confounding factors for many of the newer one-party states which will be discussed later, then these three categories account for 64.4 percent of the total in one-party states, 74.4 percent in two-party states and 73.9 percent in multi-party countries. This suggests that the creation of subversion surrounds structures and persons who are related in some fashion to the distinctly corporate aspect of a country's existence. Government and military provide the organizational structure through which nations attain their corporate existence and seem imbued with larger political significance and, accordingly, those who would subvert those sacred national purposes. Foreigners, on the other hand, relate to the corporate nation in a different manner. The very definition of foreigners, as outsiders and non-members of the national collectivity, is derived from their relationship to the corporate nation as a whole.

Multi-party states discover a very large proportion (42 percent) of their subversion among foreigners. This could reflect

Table 2. Percent Distribution of Witch-Hunting Activities by Institutional Area and Political Party System

Total	100.0	2076	100.0	641	100.0	360

the low degree to which their institutional structures are imbued with larger political significance. These countries, as nation-states, have a corporate existence, although they do not formally express as much of their distinctly corporate interests as two- and one-party states. Accordingly, sacred national purposes are not as extensively infused into their institutional structures and, consequently, they conduct much of their witch hunting outside their institutional infrastructure, e.g., among foreigners.

The percentages among the general institutional categories, Education, Economy and Intellectuals, are all quite similar. There is, though, a large discrepancy between the proportion of witch hunting centering on persons from the general category of religious groups and institutions for one-party countries (22 percent) and two- and multi-party countries (2 percent). This high percentage for one-party states could reflect the church-state struggles involved in the nation-building process of those new states which emerged following the Second World War. Partial evidence for this is found in comparing the amount of witch hunting which occurred during the early 1950-1955 period for new and older one-party states, with the latter having already passed through many of the pangs of nation-building. The new states (China, East Germany, Albania, Bulgaria, Czechoslovakia, Hungary, Poland, Rumania and Yugoslavia) averaged 73 percent of their within-religious-institutions witch hunting during the 1950-1955 period. One-party states estab-

lished before 1945 (the USSR, Spain and Portugal) averaged only seven percent of their within-religious-institutions activity during this early period. The new states also accounted for some 86.6 percent of all one-party witch hunting around religious institutions which further suggests that most of this activity was tied to the problems of newly emerging states.

Subversion within Government

We also can examine the proportion of witch hunting within the four sub-categories composing the general area of government. Table 3 shows that the vast proportion of witch hunting in government is concentrated within national bureaucracies (one-party, 63.4 percent; two-party, 78.8 percent; multi-party, 71.1 percent). There are, though, some interesting differences. As the political representation of the corporate national interest is compromised with the increasing representation of constituent group interests—that is, moving from one- to multi-party—the proportion of subversion discovered around the national executive officer, who represents the interests of the collectivity as a whole, gradually decreases (one-party, 20 percent; two-party, 10.4 percent; multi-party, 1.9 percent). The inverse relationship holds for the proportion of subversion discovered within national legislatures. As the representation of constituent interests increases, the proportion in legislatures increases (one-party, 4.3 percent; two-party, 6.1 percent; multi-party, 11.3 percent). It seems that where the expression

Table 3. Percent Distribution of Witch-Hunting Activities within Government by Political Party System

Government	One-Party		Two-Party		Multi-Party	
	Percent	N	Percent	N	Percent	N
National Executive Officer	20.0	70	10.4	22	1.9	1
National Bureaucracy	63.4	222	78.8	167	71.7	38

of the nation's corporate interest is paramount (one-party) the office which stands for the collectivity as a whole, the national executive officer, is the source of more subversive activity (20 percent) than the legislature (4.3 percent), which is the structure representing constituent group interests. Conversely, where the collectivity is structured so that constituent interests are expressed at the expense of the corporate national interest (multi-party), then legislatures have a higher proportion (11.3 percent) than the national executive officer (1.9 percent), who represents the now-compromised corporate interest. Finally, two-party countries express less corporate interests than one-party but more than multi-party. Consequently, they have more witch hunting around their executive officer than multi-party, but less than one-party countries, and more in their legislatures than one-party, but less than multi-party countries.

SUMMARY AND CONCLUSION

Although the most extreme instances of political terror and witch hunting are associated with totalitarian regimes, the ritualistic search for imaginary enemies should be conceptualized as a *variable*, not the singular property of totalitarian states. The substance of the charges and

accusations and the kinds of ritual may vary from country to country, but the sociological process is identical. Nations, as corporate entities, are all searching for the same thing: the mythical enemy which stands in symbolic opposition to the collectivity as a corporate whole.

The perpetuation of social reality through the complex interaction of ritual and a mythical universe populated with all sorts of extraordinary spirits and forces is similarly not the sole characteristic of primitive religious systems. The penetration of the sacred into daily reality is also a *variable*. Modern men also mingle and walk among their gods and find themselves in mortal combat with the mythical forces of Nature and History or The People and The Nation. These are Durkheimian representations of the corporate reality of modern societies. The more corporate reality that is present, the stronger, more clearly defined and more closely merged with everyday reality are those symbolic representations which mirror that corporate reality. Daily life becomes filled with transcendent political significance and, simultaneously, the enemies of the sacred purposes. The ritual creation of oppositions to representations of corporate social reality is one of the fundamental forms of the modern religious life.

SOCIAL REFORM ORGANIZATIONS AND SUBSEQUENT CAREERS OF PARTICIPANTS: A FOLLOW-UP STUDY OF EARLY PARTICIPANTS IN THE OEO LEGAL SERVICES PROGRAM*

HOWARD S. ERLANGER

University of Wisconsin, Madison

American Sociological Review 1977, Vol. 42 (April):233-248

This paper considers the extent to which participation as a salaried professional in a reform-oriented organization affects the participant's subsequent career. This issue is studied in the context of one such organization, the OEO sponsored Legal Services Program, which was probably the largest and best known organization oriented to the redistribution of professional services in the late 1960s. Because of the paucity of literature on the consequences of participation in reform organizations, a related literature, that of the consequences of participation in the student movement of the sixties, is drawn upon for insight, yet also critically examined.

Comparison of the subsequent careers of 228 lawyers in Legal Services in 1967 to those of 981 other lawyers who were practicing law in 1967 indicates that participation in the program has an important effect on both the distribution of professional services and the rendering of reform-oriented pro bono (free or reduced fee) work. In contrast to previous studies, the explanation offered here differentiates between various components of socialization. In addition, the importance of job market factors is stressed. A further difference from previous work is the consideration, albeit brief, of the effects of variation in experience in the organization.

In the study of social reform movements and organizations, a good deal of attention has been paid to the

characteristics of participants at the time of entry, but relatively little to the effects of participation on the subsequent careers of participants. There are many reasons for this; most obviously, current participants are relatively easy to locate, while former participants are not. In addition, much of the literature on participation relates to the social reform activities of the 1960s, for which it is only now practical to collect follow-up data.

The activism of the 1960s was most evident among college youth; hence, there is

* This paper is part of a broader study of legal rights activities in which I am collaborating with Joel F. Handler and Ellen Jane Hollingsworth. I am grateful to them and to our earlier collaborator, Jack Ladinsky, for their extensive work on all phases of the project; to James Fendrich, Thomas McDonald, Gerald Marwell and, especially, Felice Levine for their comments on an earlier draft; to Hal Winsborough, Arthur Goldberger and Robert Hauser for methodological advice; and to Irene Rodgers, Pramod Suratkhar, Anna Wells and Nancy Williamson for research and programming assistance. This work was supported by funds granted to the Institute for Research on Poverty at the University of Wisconsin by the Office of Economic Oppor-

tunity pursuant to the Economic Opportunity Act of 1964. Responsibility for what follows remains with the author.

a large literature on the characteristics of participants in the student movement,¹ and there is now a small literature on the subsequent activities of these activists (Fendrich, 1974; Fendrich and Krauss, 1975; Krauss, 1974; Demerath et al., 1971; Greene, 1970; Maidenbergh and Meyer, 1970).² This literature on the subsequent attitudes and activities of college activists is rather eclectic and is based on small samples, but it is generally consistent in indicating that former student activists have retained relatively radical attitudes, have generally continued to participate in protests (although not as actively as in the sixties) and have tended to avoid business-oriented careers in favor of jobs in the knowledge and human services sectors. Taken together, the studies tend to disconfirm the maturation hypothesis, which holds that activists outgrow their radicalism; they also are inconsistent with the hypothesis that radicals become disillusioned with society after being thwarted in their attempts at radical social change.³ (For discussion of these hypotheses, see Fendrich, 1974 or Krauss, 1974.) However, as discussed later, this literature has been less successful in dealing with the question of whether the subsequent careers are a result of experiences in the movement or of preexisting ideology, and it has not dealt adequately with the process through which movement experiences may have affected subsequent careers.

In addition to the very visible reform *movements* like the student movement, the sixties also were marked by the formation of many reform-oriented *organizations* that offered full-time employment in jobs having a direct impact on the situa-

tion of relatively powerless groups. Such organizations include Vista and the Peace Corps, as well as several offering reform-oriented variations of traditional professional careers (see, e. g., Gross and Osterman, 1972; Borosage et al., 1970). This paper analyzes the subsequent careers of early participants in one such organization, the Legal Services Program sponsored by the Office of Economic Opportunity. The primary question is whether such reform-oriented programs are essentially transitory experiences, with participants simply taking time out to "do good" for the indigent citizen or, alternatively, whether they can act as channelling mechanisms, substantially redirecting the careers of professionals who pass through them and thus effecting a redistribution of professional services in society.

THE ORGANIZATION

Although the 1960s marked a spurt in reform-oriented efforts in both the public and private sectors of the legal profession, the Legal Services Program has been the mainstay of the day-to-day efforts to deal with the legal needs of underrepresented citizens (Moonan and Goldstein, 1972). Legal Services was formed in 1965 under the auspices of the Office of Economic Opportunity, but the first full year in which it had a large number of programs operating was 1967, when it included about 1,200 lawyers.⁴ From the beginning, the program has tried to shift the balance of power in the legal system in two ways (Finman, 1971; Griffin, 1967; Stumpf, 1968). First, it has tried to increase the power of indigent citizens by pursuing a strategy of "test case" litigation. Suits have been brought—often against government agencies—in the name of a client but with implications for all people in a similar situation (see, especially, Cahn and Cahn, 1964). Some major cases of this type have been won by Legal Services lawyers (see, e.g., Miller, 1973), and these cases have been the source of much polit-

¹ There are several reviews and interpretations of this literature, including Lipset (1968) and Lipset and Altbach (1966). A few of the more important individual works are Flacks (1967), Keniston (1968) and the critique by Finney (1971).

² All of the studies cited are of the U.S. student movement, except that of Krauss, which is on Japanese activists. Krauss' study contradicts a variety of oft-quoted journalistic accounts, some of which have found their way into the sociological literature.

³ Of course, these dropouts would be very unlikely to be reached in a sample survey. See, for example, the discussion in Carey (1968).

⁴ The history of the Legal Services Program is discussed in more detail in a separate publication (Handler et al., forthcoming).

ical opposition to the program.⁵ The second strategy, and the one which has been dominant in terms of time spent per lawyer, has been that of representing indigent citizens in individual matters without special attention to broader consequences of the case. This work has had an impact simply because of the increased representation of people who previously were relatively helpless against those individuals and agencies with access to the legal system.

METHOD

Analysis in this paper focuses on the differences between 1967 Legal Services lawyers and the other lawyers in the bar in terms of job characteristics six years later.⁶ These characteristics include type of practice setting, type of client served and, for lawyers in private practice, the rendering of reform-oriented *pro bono* (free or reduced fee) work. The data for Legal Services lawyers are from a stratified random sample of all known participants in the program in 1967, interviewed in the fall of 1973.⁷ The responses from the strata are weighted to correspond to the estimated true distribution in the population. The sample is biased (to an unknown degree) in that it underrepresents persons with short tenure in the program, persons who have dropped out of the legal profes-

sion since leaving Legal Services, and persons who are too mobile to be located in spite of our extensive inquiries through a variety of sources.

Characteristics of Legal Services lawyers are compared to those of a stratified random sample of practicing lawyers, interviewed in fall or spring, 1973-74.⁸ This sample was drawn primarily from the Martindale-Hubbell Directory of Lawyers (1972) but, since there is evidence (Ladinsky, 1964) that this directory underrepresents solo practitioners, lawyers not in private practice and, especially young lawyers, a supplementary sample was drawn from other sources. This supplementary sample was constructed by first selecting fifteen states at random (with the probability of being chosen conditional on the number of lawyers in the state) and then sampling from the most complete list of lawyers available for that state. Responses are pooled and weighted to correct for the various sampling ratios employed. Lawyers who retired before 1967, who received law degrees after 1967, or whose 1967 job was in Legal Services are dropped from this control group.

This paper reports on 228 white male Legal Services lawyers and 981 white males in the bar. Blacks and women are excluded from the analysis because of their small sample size, despite the fact that each comprised about an eighth of the participants in Legal Services in 1967 (Erlanger, 1976). (White males, black males and white women who were in Legal Services all appear to have quite different distributions of 1973 job. See footnote 16.) Because of the restriction to white males, the pronoun "he" is used in this paper.

CRITICAL ISSUES IN THE STUDY OF THE EFFECTS OF PARTICIPATION IN SOCIAL REFORM ORGANIZATIONS

Given the small empirical literature on the consequences of participation in reform organizations (Zald and McCarthy, 1975), the literature on the student movement is the most relevant guide to an inquiry on this subject.

⁵ Such opposition contributed to the removal of the program from the OEO and the creation of an independent Legal Services Corporation to oversee it (Handler et al., forthcoming; Hiestand, 1970).

⁶ The target job is the predominant job held at the time of the interview; this is not necessarily a change from the job held in 1967. Many lawyers hold more than one job simultaneously (one of our respondents reported holding four), and the predominant job is defined as the one in which the respondent spent 60 percent or more of his time or earned 60 percent or more of his income in the preceding year. Ninety-five percent of all respondents having more than one job could be classified in this way. For the other five percent, a predominant job was designated on the basis of time and income shared among jobs. Analysis indicates that concentration on the predominant job does not affect the conclusions drawn in this paper.

⁷ Sampling and weighting procedures are discussed in greater detail in Handler et al. (forthcoming). All interviews were conducted by telephone by the staff of the Wisconsin Survey Research Laboratory. The average interview lasted over an hour.

⁸ Interviewing procedure was the same as for the Legal Services lawyers.

The Problem of Self-Selection

Other than small sample size, the most obvious problem in the literature on the effects of participation in the student movement is the absence of controls for factors predating participation. This problem is due primarily to the journalistic nature of many of the studies, although it also appears in the only book length scholarly study (Krauss, 1974).⁹ In the study of the effects of student activism, Fendrich's (e.g., 1974; Fendrich and Krauss, 1975) papers on subsequent political attitudes and behavior are the only ones that systematically use control variables.

Since people are not randomly assigned to participation in reform movements, the problem of self-selection can never be fully dealt with,¹⁰ and there is always the possibility that some unobserved variable renders the observed relationships spurious even when control variables are used.¹¹ Some control variables such as college major or prior political participation, along with the participation and its apparent effects, may be consequences of an unobserved variable such as "orientation to social reform." It is necessary, therefore, to control for variables that occur prior to the unobserved variable—in this case, variables such as religion of family of origin, parents' SES or parents' politics. If these controls do not substantially reduce the relation between participation and subsequent activity, then the critic is obliged to suggest an unobserved variable that is substantially independent

of such parental characteristics. In the prior literature, parental characteristics have not been controlled; appropriate variables are, however, included in the present analysis. In addition, self-selection is less of a factor in reform organizations offering salaried positions, because the factors leading to participation are more varied. Thus, compared to a more explicitly political movement, a reform organization does not begin with as committed a group of participants.

Conceptualization of the Problem at Issue

The major multivariate analyses of the effects of student activism have been framed in terms of the question, "How much variance in current political attitudes or political behavior can be explained by prior student activism, net of controls?" (Fendrich, 1974; Fendrich and Krauss, 1975). The difficulty with this conceptualization is that a variable like student activism or participation in Legal Services cannot explain any meaningful part of the variance in current attitudes or behaviors (measured for a whole population), because the rate of activism or participation is so low.¹² For example, in 1967 less than one-half of one percent of the bar was in Legal Services. For just this reason, researchers studying the effects of participation sample the participants and the control group separately.

Now if one has heavily oversampled one group, one must decide how to weight the responses. With no correction for the different sampling ratios, variance is artificially created on the oversampled variable, and the variance is changed on all of the variables correlated with it. As an example of the problem, consider the effects of different weights on the variance explained in the "status of practice" of lawyers engaged in private practice. (This variable, which indicates success by traditional criteria, will be defined and discussed in detail below.) In Example 1 of Table 1, responses of Legal Services lawyers are weighted so that they consti-

⁹ This problem is remedied to a certain extent in Krauss' more recent work (Fendrich and Krauss, 1975).

¹⁰ In the study of the effects of particular programs, there is occasionally a way to do a more controlled study. If, due to a lack of positions, the program turned away candidates that otherwise it would have taken, and if those turned away are initially similar to those accepted, then a good control group is generated.

¹¹ See the discussions of regression artifacts in Campbell and Erlebacher (1970), Riecken and Boruch (1974: 174ff) or Weiss (1972). Goldberger (1972) has, however, formally set out at least one plausible model in which regression artifacts would not occur. For a more detailed discussion of regression artifacts and other issues in the evaluation of social programs, see the papers in Bernstein (1975).

¹² For discussion of other limitations of approaches which seek to explain the variance, see Duncan (1975:63-6).

Table 1. Variance Explained by Independent Variables under Different Weighting Schemes^a

Independent Variables	Legal Services Lawyers, as Percent of Total Sample		
	Example 1 0.3%	Example 2 13%	Example 3 50%
(1) Participation in Legal Services	R ² = 0%	R ² = 7%	R ² =17%
(2) Participation in Legal Services Plus Eight Controls, Entered as Groups of Dummy Variables	R ² =11%	R ² =15%	R ² =23%

^a White males in private practice only; N=713. Dependent variable is "status of practice" index. R² corrected for degrees of freedom.

tute 0.3% of the lawyers in private practice; in example 2, no special weights are applied,¹³ and the difference in sampling ratios results in Legal Services lawyers comprising about 13% of the lawyers; in example 3, Legal Services lawyers are reweighted so that they comprise 50% of the lawyers. As the table clearly shows, the weights make an important difference. Moreover, only example 1 accurately estimates the variance explained by participation in Legal Services.

The variation in the R² depending on the weighting scheme does not necessarily mean that the R² must be totally ignored when certain variables are artificially skewed, as an examination of R²s can serve a heuristic function. However, it does seem to be incorrect to define the task at hand as the determination of the contribution of the participation variable to the total variance explained in the dependent variable. An alternative approach to conceptualizing the research issue when participants have been oversampled, and the one which will be used in this paper, is to examine the unstandardized regression coefficients to see (1) whether participation has a substantively meaningful effect on the dependent variables and (2) whether control variables have an effect on those raw coefficients. Unlike standardized coefficients, unstandardized ones do not vary with the different weighting schemes, except for rounding error.

Varieties of Experience

The literature on student activism has not explored in any detail the possibility that the effects of participation may vary with differences in the activist experience. For example, the leaders of the various organizations, marches, etc. presumably had a much deeper involvement than most followers, and both leaders and followers varied in the length of time they were active. Further, participants differed in the types of activities they engaged in (especially legal versus illegal), the types of issues they addressed, the degree of contact with the police and the degree of official sanction (if any) they experienced. Similarly, in Legal Services, participants differed on such variables as the extent of direct contact with the poor, the types of cases dealt with, and the courts in which they appeared.¹⁴ Thus, an important issue is the extent to which the Legal Services experience in general, rather than the specific varieties of it, affects the individual participants.

Process through which Participation Affects Subsequent Attitudes and Behavior

Previous literature has assumed that if it can be shown, first, that former activists are different from others in their cohort and, second, that these differences are not spurious, then the cause of the correlation between participation and subsequent at-

¹³ As discussed above, Legal Services participants and nonparticipants were sampled separately using a stratified design and unequal sampling ratios. Weights to correct for this design were retained in the analysis.

¹⁴ Except for Table 2, all analysis is restricted to lawyers who left the program. However it should be noted that the program is flourishing today in much the same form as in 1967 (Handler et al., forthcoming).

titudes or behavior is socialization in the movement. However, comments by informants in the present study indicate that elaboration of the process of socialization is necessary and that when occupational careers are considered, additional mechanisms are clearly relevant. These additional mechanisms include networks yielding information about potential jobs and clients and employer preferences in hiring. It seems plausible that similar processes have affected former student activists.¹⁵

THE SUBSEQUENT CAREERS OF LEGAL SERVICES LAWYERS

Since the Legal Services Program has been funded continuously for over ten years and since it offers permanent employment, it is possible that most of the early participants are still there. However, there has been a rather high rate of turnover (Erlanger, 1976). A third of the (white male) lawyers in Legal Services in 1967 left before the end of their third year, another quarter left by their fifth year, and only 29% were still there when our data were collected in fall, 1973. Moreover, the data indicate that it is the lawyers with prior involvement in social reform activity, those working in the reputedly "excellent" offices, and those from more liberal backgrounds who tend to leave earlier (Erlanger, 1976). The first issue for analysis is, then, where did they go?

Type of Practice

Compared to nonparticipating lawyers, lawyers who participated in Legal Services in the early years had quite different jobs in 1973. As Table 2A shows, former Legal Services lawyers are less likely to be in private practice.¹⁶ Historically, the

overwhelming majority of lawyers have been in private practice (Blaustein and Porter, 1954); virtually all well-known lawyers spend most of their careers in private practice (although they will, on occasion, put in a period of high-level government service); and private practice certainly is potentially the most lucrative form of practice.

However, the difference in propensity to be in private practice is only a small part of the story. More fundamentally, whether in private practice or not, former Legal Services lawyers serve a different type of client and do a different type of work. Tables 2B and 2C show this clearly.¹⁷ Eighty-six percent of former Legal Services lawyers in private practice (compared to 64% of the bar) are either in solo practice or in very small firms and, consequently, deal almost exclusively with the affairs of individuals with low or moderate incomes and of relatively small businesses (Handler et al., forthcoming). Only a small percentage of former Legal Services lawyers are in firms of ten or more members, and none in our sample has moved into the major firms that often

9%; firm of 2-4 members, 9%; firm of 5-9 members, 4%; counsel for business corporation, 6%; university faculty, 14%; activist government agency, 5%; legal rights job, 1%; other salaried job, 1%; non-law job, 14%; retired or unemployed, 1%. Note that percentages based on such a small N are unstable, especially when the data are weighted. The control group sample yielded only eight nonwhite lawyers, too small an N for analysis.

The job distribution for white women also is based on small Ns, 22 for the Legal Services lawyers and 28 for the bar. For the list that follows, the Legal Services percent is shown first, followed by a slash and then the control group percent. Unlike the comparisons for white males shown in Table 2, the data here are not standardized by year of graduation. Same Legal Services job, 8%/-; different Legal Services job, 2%/0%; solo practice, 42%/15%; firm of 2-4 members, 2%/16%; firm of ten or more members, 2%/6%; counsel for business corporation, 1%/4%; university faculty, 4%/11%; other salaried job, 6%/20%; non-law job, 0%/11%; retired or unemployed, 33%/16%.

¹⁷ Preliminary analysis of the data using controls for year of graduation revealed no important interaction effects. However, since the former Legal Services lawyers are much younger than the control group (Erlanger, 1976), for all percentages shown (in text and tables) the year of graduation of lawyers in the control group has been standardized so that the distribution of that group matches that of the Legal Services lawyers.

¹⁵ The characteristic most likely to affect employer judgments of a former student activist is probably the existence of an arrest record, which in some quarters was virtually a membership badge in the movement. Business employers are much more likely than those in the human services sector to reject an applicant solely on those grounds.

¹⁶ The current positions of the twenty-nine male nonwhite lawyers who were in Legal Services in 1967 is as follows: in same Legal Services job, 33%; in different Legal Services job, 2%; solo practice,

Table 2. Jobs Held, 1973-1974 ^a

	Legal Services Lawyers	Lawyers in Bar
A. Type of Practice		
Same Legal Services Job as 1967	22% (41)	... ^b
Other Legal Services Job	7% (14)	0% (1)
Private Practice of Law	40% (92)	67% (621)
Other Jobs	31% (77)	31% (305)
Retired; Unemployed	1% (4)	2% (54)
	101% (228)	100% (981)
B. Distribution within Private Practice		
Solo Practice	43	27

^b Not applicable to lawyers in bar.

have over 100 lawyers and handle the affairs of the major corporations and of wealthy individuals (Smigel, 1969). By contrast, 18% of the bar are in firms with ten or more lawyers (Table 2B).

Similarly, former Legal Services lawyers who are not in private practice are heavily concentrated in nonbusiness pursuits. Fifteen percent of these lawyers have remained in "legal rights" work (Borsage et al., 1970; Marks, 1972), with a public defender's office, a public interest law firm, a social reform-oriented foundation or similar type of organization; another 16% work for an activist government agency, such as the Civil Rights Division of the Department of Justice. Ten percent are employed primarily as law professors, usually teaching at least one nontraditional course such as welfare law, consumer protection, etc. Forty-three percent are in miscellaneous salaried posi-

tions, mostly in federal, state and local government, while only 16% are staff counsel for a business corporation or working in a non-law (usually business) job. As Table 2C shows, this distribution is very different in the bar, for which 60% of lawyers not in private practice work either in a non-law job or as a salaried counsel to a business corporation. (The percent of law faculty is roughly the same in the bar, but further analysis indicates that the courses taught are different.)

Further Differences within Private Practice

Firm size often is used as an indicator of the type of work engaged in by a lawyer in private practice (Carlin, 1966; Ladinsky, 1963), but it is really a proxy for several aspects of practice such as type of clients (business rather than individuals relatively wealthy businesses and individu-

als), income, type of courts appeared in (federal and state appeals, rather than lower state and county courts), physical work setting (large firms generally have posh offices and are located in the "better" parts of town), types of cases (contracts, trusts, tax, etc. as opposed to matrimonial, criminal or personal injury); etc.

In order to incorporate more of the variables which traditionally have been seen by both lay persons and lawyers as defining a lawyer's status, we have developed a "status of practice" index based on firm size, income level of business and individual clients and professional income.¹⁸ Table 3 shows a sharp differentiation between former Legal Services lawyers and other lawyers in private practice when these traditional criteria of professional status are used. Although actual scores on the "status of practice" index range from 0 to 13, half of the former Legal Services lawyers, as compared to only 19% of other lawyers in private practice, score 0, 1 or 2. Similarly, only 5% of Legal Ser-

¹⁸ The status of practice index is the sum of scores on three separate indices, each of which was first converted to a z-score based on the distribution for the control group. The three subindices were: (1) log of firm size (solo practice = firm size of one), (2) income from the practice of law during the preceding year (corrected for multiple jobs) and (3) a "status of clients" scale, based on the income of business and individual clients, weighted by the proportion of time spent on each type of client. A score of three on one of these subindices indicates that the lawyer's raw score was within one standard deviation of the control group mean on that index. One point was then added or subtracted for each standard deviation above or below the mean in which the respondent's score fell, up to a maximum of three points. A score of zero on a subindex thus indicates that the score was three standard deviations below the mean, a score of six indicates that it was three standard deviations above the mean. Since the distributions on all the subindices were heavily skewed to the bottom of the scale, the z-score technique is technically not appropriate. However it was used because it generated a score which could meaningfully be added to those on the other subindices. Experimentation with different scoring methods and analysis of the subindices independently did not affect the findings. The index, which is similar to those used in previous work (Carlin, 1966; Handler, 1967), is discussed in more detail in Handler, et al. (forthcoming). One advantage of such an index is that it allows for the situation in which one or a few lawyers practice on a small scale numerically, but on a large scale in terms of impact (see, e.g., Goulden, 1972; Green, 1975).

Table 3. Score on "Status of Practice" Index *

Score on Index (range 0-18)	Cumulative Percentage	
	Former Legal Services Lawyers	Lawyers in Bar
Less than 2	12	7
Less than 3	50	19
Less than 4	78	37
Less than 5	89	56
Less than 6	95	72

Less than 9	100	94
Less than 14	100	100
(N)	(92)	(621)

* White males in private practice only. Distribution of year of graduation of lawyers in bar standardized to that of former Legal Services lawyers.

vices lawyers, as compared to 28% of others, score six or more. Since the Legal Services lawyers have social and educational backgrounds comparable to lawyers in the bar (Erlanger, 1976), they would be expected to have similar practices. Differences of this magnitude in the kind of practice taken up thus, in essence, represent a redistribution of legal services away from the upper-middle and upper classes toward the middle, lower-middle and lower classes.

A second effect of Legal Services on the type of subsequent private practice is the extent to which clients of minority backgrounds are served. Former Legal Services lawyers are much more likely to have a large percentage of minority (primarily black) clients. Data standardized by year of graduation show that close to half (45%) of the lawyers in private practice have only a few clients from minority groups; for former Legal Services lawyers, the figure is 26%. Similarly, only 12% of the private practice bar, as compared to 29% of former Legal Services lawyers, have a practice in which a third or more of their clients are members of minority groups.

A third effect is on type of *pro bono* work done by lawyers. The obligation to do *pro bono* work has long been part of the ethic of the legal profession, but historically the extent and range of this type of work has been quite limited (Carlin et

al., 1966; Marks, 1972). Even today the average lawyer spends a rather modest part of his or her time on *pro bono* work, generally performs this work for traditional clients such as relatives, friends of clients, church groups, charities and indigent individuals, and generally uses a case-by-case approach, drafting legal documents, rendering advice and appearing in criminal courts (Handler et al., 1975; Lochner, 1975). Our data indicate that former Legal Services lawyers are more likely than other lawyers to do *pro bono* work; but, most important, they are more likely to take on clients and cases oriented toward law reform rather than individual adjudication—for example, cases involving welfare rights or consumer issues, or clients who are migrant farm workers or inmates of mental hospitals. Data standardized by year of graduation show that in the year prior to being interviewed, 42% of former Legal Services lawyers, as compared to 27% of other lawyers in private practice, did *pro bono* work oriented to social reform (Handler et al., forthcoming).

Tests for Spuriousness

In a quasi-experimental design, spuriousness can never be totally ruled out; however, as discussed earlier, the present analysis is strengthened by the presence of indicators of the political and social reformist orientations of the respondent's family of origin. These variables include father's political stance, parents' participation in social reform organizations, mother's religion and father's occupation. (Several other indicators also were available, but they did not affect the findings reported below.) For the respondent himself, data were collected on prior political activity, year of graduation from law school and educational characteristics (type of law school attended, class standing), all of which may be expected to affect the type of practice a lawyer enters. Although the relationships among these control variables as well as the direct and indirect effects of these variables on current job would be of some substantive interest, these considerations are not rel-

evant to the task at hand.¹⁹ Rather, this analysis seeks only to gauge the effect of participation in Legal Services on the lawyer's subsequent career, net of the effect of these controls. Hence, in the analysis of spuriousness, control variables were, for the most part,²⁰ entered into the model in one group. The presentation here will deal only with lawyers in private practice. Analysis of the entire sample, using other dependent variables, yielded similar conclusions.

Comparison of rows (a) and (b) in Table 4 shows the simultaneous effect of all controls except prior job on the three characteristics of private practice previously discussed.²¹ The table indicates that these control variables have little effect on the tendency for Legal Services lawyers to avoid those types of practice which traditionally have been accorded high status and to do reform-oriented *pro bono* work.

¹⁹ One important finding which emerges is that in this national data set, social background variables do not have nearly as strong an effect on status of practice as would be expected from earlier studies in individual cities (e.g., Carlin, 1962; 1966; Ladinsky, 1963; 1967).

²⁰ When Legal Services lawyers are compared to the bar as a whole, prior job is omitted. For reasons explained below, prior job is added to the other controls only after lawyers with stable job histories are dropped from the control group.

²¹ The regressions were run with weighted data to correct for disproportionate sampling ratios for strata within the Legal Services sample and within the bar sample. However, the most efficient use of the available data dictated no further use of weights to correct for the oversampling of Legal Services participants.

Tables 4 and 5 are based on dummy variable regression (multiple classification analysis), a variant of the general linear model (Andrews et al., 1967; Cohen, 1968; Melichar, 1965). A global test for interactions in which each category of each control variable was interacted with the variable "participation in Legal Services" indicated that, for each dependent variable, addition of the interaction terms did not significantly increase the corrected R^2 .

For the dichotomous variable "does social reform *pro bono* work," analysis also was done using a logit model (Theil, 1971), a log linear model which yields more accurate estimates than regression when the dependent variable is dichotomous. A maximum likelihood estimation procedure was used. This analysis yielded stronger findings than those reported in the text for the regression analysis; the Legal Services effect was actually somewhat greater with the control variables than without. The regression findings are presented in the tables because they are more easily interpreted.

Table 4. Effect of Participation in the Legal Services Program on Characteristics of Subsequent Private Practice I^a

	Dependent Variables		
	Status of Practice (range 0-18)	Percent Minority Clients (range 0-100)	Does Social Reform <i>Pro Bono</i> Work (range 0-1)
Mean Score, Lawyers in Bar	5.0	14	.24
Mean Score, Former Legal Services Lawyers			
a) Without controls	3.2	25	.42
b) Controlling for year of graduation and background and educational variables ^b	3.3	23	.40
c) Controlling for variables above, ^b plus status of practice index	...	21	.39

^a White males only; N=713.^b Variables entered as sets of dummy variables in a multiple classification analysis.

Percent minority clients is reduced somewhat more than the other variables, and an additional control for status of practice reduces it further. At this point, however, the difference between participants and nonparticipants in the percent minority clients is still statistically significant ($p < .005$).²² The Legal Services effect for the status of practice and *pro bono* variables seems, then, to operate primarily in an additive fashion to these control variables.

Let us now consider the effect of control for prior job on the findings for the three characteristics of private practice. Prior job is a critical control variable, since about three-fourths of the Legal Services lawyers came from another job, and one would expect the contacts and experiences of the prior job to influence the type of job held subsequently. To analyze the influence of prior job, the most appropriate control group to which Legal Services lawyers can be compared is one composed of other lawyers who changed jobs during 1965-68, a period roughly equivalent with the span of time

in which Legal Services lawyers joined the program. Since lawyers are rarely fired and tend, once established, to stay in a job for a long period of time, most lawyers are not "in the market" and their careers cannot appropriately be compared to those of the mobile lawyers.²³

The job held by a lawyer prior to making a job shift in the period 1965-1968 is a relatively good predictor of the job held in 1973-74. Lawyers who were in solo practice in the earlier period are more likely to be in solo practice or with a small firm in the later period; lawyers who were in larger firms are more likely to be in relatively large firms; etc. But the important point for the analysis here is that for two of the dependent variables (status of practice and reform-oriented *pro bono* work), the effect of participation in Legal Services is independent of the control variables (Table 5). However, when background, status of practice and prior job are all controlled, the difference in the percent of clients who are members of minority groups is no longer statistically significant (Table 5). The observed difference in percent minority clients is thus partly attributable to differences in background, education and prior job, and partly attributable to an indirect effect associated with the type of clientele served.

²² Fractional weights were used, so the significance level is not affected by artificial increase in sample size. However, the significance level is not as accurate as with a true random sample because the weighting scheme used sacrifices some efficiency in sample design. Because of the relatively large N, rather small coefficients are statistically significant. Hence, significance levels are not shown in the tables but, for small coefficients, are reported in the text for reference by the interested reader.

²³ Perhaps the findings would be more precise if various control groups were used, depending on the number of job changes since the early 1960s. Sample size does not permit this procedure.

Table 5. Effect of Participation in the Legal Services Program on Characteristics of Subsequent Private Practice II^a

	Dependent Variables		
	Status of Practice (range 0-18)	Percent Minority Clients (range 0-100)	Does Social Reform <i>Pro Bono</i> Work (range 0-1)
Mean Score, Lawyers in Bar	4.6	17	.24

a) Without controls	3.0	27	.44
b) Controlling for year of graduation and background and educational variables ^b	2.9	23	.43
c) Controlling for variables above, plus job left in 1965-68 ^b	3.0	23	.44
d) Controlling for all of the above, ^b plus status of practice index	...	19	.41

^a White males only; N=210. Legal Services lawyers are those who had a prior job; lawyers in bar are those who changed jobs in the period 1965-68.

^b Variables entered as sets of dummy variables in a multiple classification analysis.

DISCUSSION AND CONCLUSIONS

The Effects of Participation

Given the limits of quasi-experimental design, the conclusions here must be tentative; but, within these limitations, the data for white male Legal Services lawyers clearly indicate that participation in the program leads to a redistribution of service among lawyers in private practice.²⁴ Former Legal Services lawyers in private practice tend to avoid the more prestigious types of practice (as measured by the traditional criteria of type of clients, type of work setting and professional income) and they are more likely to do *pro bono* work oriented to social reform than are other lawyers of comparable background and experience. Former Legal Services lawyers who do not go into private practice also have quite different careers than their counterparts in the bar; most especially, they seem to shun corporate counsel and nonlaw jobs.

The subsequent career of the Legal Services lawyer, much like that of any worker, is affected by a mix of socialization and job market factors. The following

seem particularly important for the Legal Services lawyer. First, socialization of attitudes doubtless plays a role. In Legal Services, the lawyer learns to view the problems of the "little guy" as important, or, already holding this view, has it reinforced. But a focus on attitudes alone overlooks other important processes. A second component of socialization experienced by the Legal Services lawyer is training in the skills relevant to the legal problems of poor people, with the relative absence of training in legal skills relevant to corporations and wealthy individuals. The Legal Services lawyer, in much the same way as other lawyers who have worked in a particular area, becomes a specialist of sorts and, thus, has limited attractiveness to some potential clients, employers or colleagues and enhanced attractiveness to others.²⁵

Finally, we know from a variety of studies that job milieu has a strong effect on the type of subsequent job held.

²⁴ This is basically the pattern of subsequent jobs predicted in McCarthy and Zald's analyses (McCarthy and Zald, 1973; Zald and McCarthy, 1975) of recent trends in social reform movements.

²⁵ Major firm lawyers whom we have interviewed on this issue indicate that "bad training" is viewed as a serious problem. In addition, there is the problem of "lateral entry" to firms. Major firms find it preferable to bring in new lawyers at the bottom (i.e., fresh out of law school) or at a senior level; they do not like to bring in lawyers with a few years of experience not directly relevant to the firm's specialty.

Studies of many different occupations indicate that most jobs are obtained not through the "open market," but through information gained from personal acquaintances who have direct or indirect knowledge of the availability of a particular job.²⁶ (This does not mean that these acquaintances have influence with the potential employer but, rather, that they make a person aware that a good job exists.) Moreover, a substantial percentage of persons who change jobs are never directly in the job market, but hear of a job through informal channels at a time that is opportune for them. The reliance on informal processes is especially characteristic of lawyers, for whom formal recruitment mechanisms primarily exist only upon graduation from law school. And even lawyers practicing on their own are dependent on the same type of network for clients. The network of associations generated for a Legal Services lawyer, especially one working primarily on service cases, was very different than that of, say, a lawyer in a large firm or a lawyer working directly for a business corporation; and this very likely affected the subsequent jobs taken.

Emphasis on the socialization and job market effects of participation in Legal Services is not to deny that there could also be a self-selection effect. Such an effect would most likely operate through a prior orientation to social reform or through prior career choices. Granted, controls for these and related factors such as year of graduation, law school attended, etc. are imperfectly measured. But it is striking that together they have so little impact on the relationship between participation in Legal Services and key characteristics of the lawyer's subsequent job. Moreover, these conclusions are strengthened because of the inclusion of several indicators of characteristics of family of origin which one would expect to cause a reformist orientation. This is much preferable to a design which con-

trols only for factors which themselves may be consequences rather than causes of social reformism. As noted earlier, a critic of these conclusions must proffer an unmeasured self-selection variable which is so slightly related to those variables examined that this unmeasured variable could account for the effects found in this study.

In addition, it is important to note that the explanation presented here does not require an absence of self-selection. Rather, the argument is that, in the case of self-selection, socialization and especially the job market factors would reinforce the decision. In short, lawyers join Legal Services for a variety of reasons but, overall, participation tends to decrease the probability that they will pursue the traditional routes to success. The importance of program effects as opposed to self-selection effects also can be seen in a comparison of lawyers who stated different motives for joining the program. Legal Services lawyers gave three general types of reasons for joining—reasons which would appear to have an explicit social reform content ("I felt I had a duty to help the poor," "I wanted to work with these types of issues"); reasons which might include a social reform component (the types of cases would be "challenging," the job afforded "community contacts," etc.); and reasons which appear to include only personal factors (the desire to gain practical experience, the location of the office, the steady income). If the observed effects of participation in Legal Services were spurious, then one would expect that the effects would be strongest for those lawyers who report a reformist motivation for joining. However, there are no statistically significant differences between the three groups on the dependent variables. Moreover, insofar as there are differences, lawyers explicitly citing a social reform motivation for joining are actually somewhat *lower* than either of the other groups in both the percent minority clients served and the rendering of reform-oriented *pro bono* work.

Obviously, the argument here must be tentative, since no direct data on the socialization or job changing processes for Legal Services lawyers are available.

²⁶ See, for example, the studies reviewed by Granovetter (1974:5-6). There is no study of the job-finding process for lawyers, but studies of other professionals (e.g., Brown, 1965; Shapiro et al., 1965; Granovetter, 1974) are consistent with the description in the text.

What has been documented is a "black box" effect, and a series of processes, operating in a different mix for different people, are suggested to explain it. This is presented as an improvement over previous studies, which by and large have assumed that if participation had real effects, they must be the result of socialization of attitudes. In the future, these processes need to be sorted out and other processes hypothesized and investigated.

The Effect of Variation in Experience

One important consideration in the further analysis of the effects of participation in social reform organizations is the effect of variation in the experience of different participants. Probably the greatest difference in experience in Legal Services is between lawyers engaged in law reform and those doing service work. As noted earlier, from the outset Legal Services has had dual aims: the serving of the immediate needs of individual clients through direct adjudication of their cases and the changing of laws affecting the poor, primarily through class action or test case litigation. Those lawyers who spent a significant amount of time on law reform work experienced a very different milieu; in some local programs, they even worked out of a different office (Carlin, 1970).

A lawyer doing law reform work had substantially less direct contact with clients than did other Legal Services lawyers. Most of the time on this type of litigation is spent researching the law, preparing lengthy briefs, appearing before the court and, on occasion, preparing appeals to higher courts. In doing this work, the Legal Services lawyer may have undergone a different type of socialization than the lawyer doing service work exclusively. First, the political component of the work was different, being focused on change in the centers of power, rather than affecting a change for discrete individuals. Second, lawyers in this type of work might be expected to put a premium on meticulousness, skill in legal research and ability to draft complex briefs. For lawyers doing service work, the pressures were different. Our data indicate that

these lawyers carried very heavy caseloads, generally averaging over 100 open files at a time. With this type of workload a lawyer, no matter how conscientious, was in a situation in which every angle of a case could not be pursued and a great deal of attention could not be devoted to detail.

Different combinations of socialization, job information networks and employer preferences would seem to lead to different subsequent careers for lawyers engaged in the two types of work. One might expect differences in the type of salaried job taken, the type of client served in private practice, the extent to which minority clients are served, the extent of social reform-oriented *pro bono* work, etc. However, even with the rather large sample used in this study, examination of the effects of variation of experience is hampered by small sample size. For example, only 91 Legal Services lawyers in our sample went into private practice, which is an inadequate N for extensive analysis. Thus, this analysis must be tentative; but hopefully it will serve to suggest the importance of pursuing such differences in future research.

Only about 15% of Legal Services lawyers spent a majority of their time on law reform work, but half averaged at least one day a week. Analysis indicates that insofar as doing law reform work has an effect on subsequent career, this effect is for lawyers who did one day a week or more versus those who did less than one day a week. White male lawyers who were engaged in law reform work are less likely to be in private practice than those who did almost all service work (31% versus 49%); but, contrary to expectations, the particular non-private practice job taken does not seem to have been affected by the law reform experience. However, having done law reform work does affect the type of private practice engaged in. Lawyers who did law reform work are much more likely to be "successful" by traditional criteria. Controlling for all the variables discussed earlier (including prior job), the mean status of practice for these lawyers is 3.8, as compared to 2.8 for lawyers who did service work almost exclusively. But insofar as there are effects

of variation in experience within the organization, they are additive to the effect of the participation in the organization itself. The coefficients for both subgroups of Legal Services lawyers are still substantially different from those of lawyers who were not in Legal Services.²⁷

Consequences for the Redistribution of Professional Services

In recent years, there has been increasing concern about the distribution of legal services across the population. The services of lawyers are purchased by business corporations and affluent individuals disproportionately; not just the impoverished but also the vast middle class are underrepresented (see, e.g., Christensen, 1970; Mayhew and Reiss, 1969). This pattern also can be seen in the data from our survey, which shows that 53% of the individual clients of lawyers in private practice have incomes over \$15,000, while the census shows that only 16% of adult Americans have incomes of that amount.

The Legal Services Program directly generates a redistribution of the services of lawyers toward underrepresented groups through its rendering of service without fee on a massive scale to indigent citizens. But the analysis in this paper indicates that the program also has very important spillover effects. Legal Services lawyers apparently do not just take time off from other pursuits to work with the poor, nor are they just doing what they would have done if they had not participated. Rather, the program acts as a struc-

tural mechanism that helps to direct lawyers to a different kind of client and to different types of issues. Service to the indigent is expanded because of the greater amount of *pro bono* work performed by former Legal Services lawyers and because of their propensity to take clients and cases that challenge the status quo. Service to citizens with moderate incomes is expanded through the tendency of Legal Services lawyers to go into solo practice or into relatively small firms, which tend to serve this type of client rather than corporations or wealthy individuals. In addition, service to minority clients is increased as a concomitant of this different type of practice.

These findings indicate that the well-known "problem" of turnover in programs like Legal Services is not necessarily a problem at all. Once a cohort of professionals has stayed long enough to be affected by their participation (and analysis indicates that length of service in Legal Services is not an important predictor of subsequent practice), it may be desirable that they move out into the community and make room for a new cohort. The subtle redistribution in the type of recipients of professional services will not, in itself, be sufficient to correct the inequalities in the system, but it will be an important step in that direction.

- ²⁷ There is no way of knowing the extent to which these findings can be generalized to the study of student activism. There have, however, been hints in the literature that differences in experience are relevant. For example, Greene (1970) reports his impression that the former leaders of the Berkeley FSM are more radical than the followers, although he has no control for self-selection. Krauss (1974) begins with a separation between leaders, activists and intermittent activists, but then has to collapse categories because of insufficient N. At least one study also has indicated that variation in the intensity of experience is important; in a study of students at Kent State, Adamek and Lewis (1973:347) concluded that, in spite of the problem of self-selection, there was evidence that the "extreme social control force applied by the National Guard [at Kent State] radicalized the students most directly involved."

INSURGENCY OF THE POWERLESS: FARM WORKER MOVEMENTS (1946-1972)*

American Sociological Review 1977, Vol. 42 (April):249-268

Drawing on the perspective developed in recent work by Oberschall (1973), Tilly (1975) and Gamson (1975), we analyze the political process centered around farm worker insurgencies. Comparing the experience of two challenges, we argue that the factors favored in the classical social movement literature fail to account for either the rise or outcome of insurgency. Instead, the important variables pertain to social resources—in our case, sponsorship by established organizations. Farm workers themselves are powerless; as an excluded group, their demands tend to be systematically ignored. But powerlessness may be overridden if the national political elite is neutralized and members of the polity contribute resources and attack insurgent targets. To test the argument, entries in the New York Times Annual Index are content coded and statistically analyzed, demonstrating how the political environment surrounding insurgent efforts alternatively contains them or makes them successful.

From about 1964 until 1972, American society witnessed an unprecedented number of groups acting in insurgent fashion. By insurgency we mean organized attempts to bring about structural change by thrusting new interests into decision-making processes. Some of this insurgency, notably the civil rights and peace movements, had begun somewhat earlier, but after 1963 there were organized attempts to bring about structural changes from virtually all sides: ethnic minorities (Indians, Mexican-Americans, Puerto Ricans), welfare mothers, women, sexual liberation groups, teachers and even some blue-collar workers. The present study isolates and analyzes in detail one of these insurgent challenges—that of farm workers—in an effort to throw light on the dynamics that made the 1960s a period of dramatic and stormy politics.

Our thesis is that the rise and dramatic success of farm worker insurgents in the late 1960s best can be explained by changes in the political environment the movement confronted, rather than by the internal characteristics of the movement organization and the social base upon which it drew. The salient environment consisted of the government, especially the federal government, and a coalition of liberal support organizations. We shall contrast the unsuccessful attempt to organize farm workers by the National Farm Labor Union from 1946 to 1952 with the strikingly successful one of the United Farm Workers from 1965 to 1972.

The immediate goals of both movements were the same—to secure union contracts. They both used the same tactics, namely, mass agricultural strikes, boycotts aided by organized labor, and political demands supported by the liberal community of the day. Both groups encountered identical and virtually insurmountable obstacles, namely, a weak bargaining position, farm worker poverty and a culture of resignation, high rates of migrancy and weak social cohesion, and a perpetual oversupply of farm labor, insuring that growers could break any strike.

The difference between the two chal-

* This is part of a larger study of insurgency in the 1960s directed by Charles Perrow, Center for Policy Research, Inc., New York, and funded by NIMH, Grant No. 5 R01 MH20006-04 SSR. Field investigations by Jenkins were conducted with the aid of a National Science Foundation Dissertation Grant (Proposal/Grant No. ISOC 75-08476). We owe thanks to anonymous ASR readers for their comments on an earlier version and colleagues too numerous to mention.

lenges was the societal response that insurgent demands received. During the first challenge, government policies strongly favored agribusiness; support from liberal organizations and organized labor was weak and vacillating. By the time the second challenge was mounted, the political environment had changed dramatically. Government now was divided over policies pertaining to farm workers; liberals and organized labor had formed a reform coalition, attacking agribusiness privileges in public policy. The reform coalition then furnished the resources to launch the challenge. Once underway, the coalition continued to fend for the insurgents, providing additional resources and applying leverage to movement targets. The key changes, then, were in support organization and governmental actions. To demonstrate this, we will analyze macro-level changes in the activities of these groups as reported in the *New York Times Annual Index* between 1946 and 1972.

The Classical Model

In taking this position, we are arguing that the standard literature on social movements fails to deal adequately with either of two central issues—the formation of insurgent organizations and the outcome of insurgent challenges. Drawing on Gusfield's (1968) summary statement, the classical literature holds in common the following line of argument. See also Turner and Killian (1957; 1972), Smelser (1962), Lang and Lang (1961), Kornhauser (1959), Davies (1962; 1969) and Gurr (1970).

Social movements arise because of deep and widespread discontent. First, there is a social change which makes prevailing social relations inappropriate, producing a strain between the new and the old. Strain then generates discontent within some social grouping. When discontent increases rapidly and is widely shared, collective efforts to alleviate discontent will occur. Though there is disagreement about how to formulate the link between strain and discontent, e.g., subjective gaps between expectations and satisfactions versus emotional anxiety in-

duced by anomie, the central thrust is consistent. Fluctuations in the level of discontent account for the rise of movements and major changes in movement participation.

Recent research, though, has cast doubt on the classic "discontent" formulations. Disorders do not arise from disorganized anomic masses, but from groups organizationally able to defend and advance their interests (Oberschall, 1973; Tilly et al., 1975). As for relative deprivation, Snyder and Tilly (1972) and Hibbs (1973) have failed to find it useful in accounting for a wide variety of collective disruptions. Nor is it clear that we can use the concept without falling into post hoc interpretations (cf. Wilson, 1973:73-9).¹

In this study, we do not propose to test each of the various "discontent" formulations currently available. *A priori*, it is rather hard to believe that farm workers' discontent was, for example, suddenly greater in 1965, when the Delano grape strike began, than throughout much of the 1950s when there was no movement or strike activity. Indeed, it seems more plausible to assume that farm worker discontent is relatively constant, a product of established economic relations rather than some social dislocation or dysfunction. We do not deny the existence of discontent but we question the usefulness of discontent formulations in accounting for either the emergence of insurgent organization or the level of participation by the social base. What increases, giving rise to insurgency, is the amount of social resources available to unorganized but aggrieved groups, making it possible to launch an organized demand for change.

As for the outcome of challenges, the importance of resources is obvious. Though the classical literature has rarely dealt with the issue directly, there has been an implicit position. The resources mobilized by movement organizations are assumed to derive from the aggrieved social base. The outcome of the challenge, then, whether or not one adopts a

¹ Shifts in perceptions, treated as central by relative deprivation theorists, in our view would be secondary to the main process—changes in social resources.

"natural history" model of movement development, should depend primarily upon internal considerations, e.g., leadership changes and communication dynamics among the membership.

However, are deprived groups like farm workers able to sustain challenges, especially effective ones, on their own? We think not. Both of the movements studied were, from the outset, dependent upon external groups for critical organizational resources. Nor, as the history of agricultural strikes amply attests (McWilliams, 1939; London and Anderson, 1970; Taylor, 1975), have farm worker movements proven able to mobilize numbers sufficient to wring concessions from employers. For a successful outcome, movements by the "powerless" require strong and sustained outside support.

If this line of argument is correct, we need to contest a second thesis frequently found in the classical literature—the assertion that the American polity operates in a pluralistic fashion (cf. Kornhauser, 1959; Smelser, 1962). A pluralistic polity is structurally open to demands for change.² As Gamson (1968; 1975) has put it, the political system should be structurally "permeable," readily incorporating new groups and their interests into the decision-making process. Once organized, groups redressing widely-shared grievances should be able to secure at least some part of their program through bargaining and compromise.³ Yet our evidence shows that farm worker challenges have failed, in part, because of the opposition of public officials, and that a success-

ful challenge depended upon the intervention of established liberal organizations and the neutrality of political elites.

We can then summarize the classical model as follows. (1) Discontent, traced to structural dislocations, accounts for collective attempts to bring about change. (2) The resources required to mount collective action and carry it through are broadly distributed—shared by all sizeable social groupings. (3) The political system is pluralistic and, therefore, responsive to all organized groups with grievances. (4) If insurgents succeed, it is due to efforts on the part of the social base; if they do not, presumably they lacked competent leaders, were unwilling to compromise, or behaved irrationally (e.g., used violence or broke laws).

In contrast, we will argue that (1) discontent is ever-present for deprived groups, but (2) collective action is rarely a viable option because of lack of resources and the threat of repression. (3) When deprived groups do mobilize, it is due to the interjection of external resources. (4) Challenges frequently fail because of the lack of resources. Success comes when there is a combination of sustained outside support and disunity and/or tolerance on the part of political elites. The important variables separating movement success from failure, then, pertain to the way the polity responds to insurgent demands.

Structural Powerlessness of Farm Workers

The major impediment to farm worker unionization has been the oversupply of farm labor, undercutting all attempted harvest strikes. There are few barriers of habit or skill that restrict the entry of any applicant to work in the fields. The result is an "unstructured" labor market, offering little job stability and open to all comers (Fisher, 1953). The fields of California and Texas are close enough to the poverty-stricken provinces of Mexico to insure a steady influx of workers, many of whom arrive by illegal routes (Frisbee, 1975). Continuous immigration not only underwrites the oversupply of labor, but complicates mobilization by insuring the existence of cultural cleavages among workers.

² Note also the central role played in pluralistic interpretations by the "discontent" hypothesis. Assuming that all groups have ready access to the resources needed to mobilize, Rose (1967:249) argued: "As soon as a felt need for some social change arises, one or more voluntary associations immediately springs up to try to secure the change."

³ As the central tenet of pluralist theory, the "permeability" argument can be found in almost any presentation of the view. Dahl (1967:250) argues: "even minorities are provided with opportunities to veto solutions"; Truman's (1951) speculations about "potential groups" and Smelser's (1963:364-79) recommendations to elites for channeling "value-oriented" movements into "norm-oriented" ones both build on the assumption of a flexible political system based on a pluralistic social structure.

Furthermore, there are reasons to believe that a significant number of workers have only a limited economic interest in the gains promised by unionization. The majority of farm workers, both domestic and alien, are short-term seasonal workers. During the early 1960s, farm employment in California averaged less than three months of the year (Fuller, 1967). This means that a majority of workers are interested primarily in the "quick dollar." Imposition of union restrictions on easy access to jobs would conflict with that interest. And for the vast majority of farm workers, regardless of job commitment or citizenship status, income is so low as to leave little economic reserve for risk-taking. Since a major portion of the year's income comes during the brief harvest period, workers are reluctant to risk their livelihood on a strike at that time.

In addition to these structural restraints on collective action, there were the very direct restraints of the growers and their political allies. The California Department of Employment and the U. S. Department of Labor have long operated farm placement services that furnish workers for strike-bound employers. Insurgent actions that directly threaten growers, like picket lines and mass rallies, consistently have been the target of official harassment. Though never returning to the scale of the "local fascism" of the 1930s (McWilliams, 1942; Chambers, 1952), grower vigilante actions are not uncommon.

Bringing these considerations to bear on the comparison of farm worker challenges, there is reason to believe that circumstances were slightly more conducive to the mobilization efforts of the UFW. Between 1946 and 1965 farm wage rates rose slightly and a few public welfare benefits were extended, at least within California. Presumably, farm workers were slightly more secure economically by the mid-1960s. More significant, though, were changes in the social composition of the farm labor force. During the late 1940s farm workers in California were either "dustbowlers" or Mexican *braceros* (government-imported contract workers); by the mid-1960s the California farm labor force was predominantly

Mexican-descent, short-term workers, most of whom only recently had migrated across the border. Not only were linguistic-cultural cleavages somewhat less pronounced, but these new immigrants were more likely to settle and develop stable community ties than their "Okie" predecessors.

Also, the United Farm Workers pursued a mobilization strategy better designed than that of the NFLU to sustain the participation of farm workers. From its inception, the UFW was an Alinsky-styled community organization. The primary advantage was that it offered a program of services and social activities that did not depend upon first securing a union contract. Members developed an attachment to the organization independent of the immediate gains that might derive from any strike. Though the National Farm Labor Union had taken limited steps in a similar direction, its program remained primarily that of the conventional "business" union, promising wage gains and better working conditions rather than social solidarity and community benefits.

But the critical issue is whether differences in either the structural position of farm workers or the mobilization strategy adopted by the movements affected either dependent variable. As we shall see, the impetus for both of the challenges came from the interjection, into an otherwise placid situation, of a professionally-trained cadre backed by outside sponsors. Farm worker discontent remained unexpressed in any organized way until outside organizers arrived on the scene.

As for the question of challenge outcome, despite the UFW's advantages, it experienced no more success in strike efforts than did the NFLU. Where the NFLU had to contend with the semi-official use of *braceros* as strikebreakers, the UFW had to deal with vastly increased numbers of illegal aliens and short-term workers crossing the picket lines. The combination of structural constraints and direct controls insured that neither union was able to mobilize a sufficiently massive social base to be effective.

What separated the UFW success from the NFLU failure was the societal re-

sponse to the challenges. The NFLU received weak and vacillating sponsorship; the UFW's backing was strong and sustained. Under the pressure of court injunctions and police harassment, the NFLU boycott collapsed when organized labor refused to cooperate. By contrast, the UFW boycotts became national "causes," receiving widespread support from organized labor and liberal organizations; though official harassment remained, the UFW did not deal with the same systematic repression confronted by the NFLU. The success of a "powerless" challenge depended upon sustained and widespread outside support coupled with the neutrality and/or tolerance from the national political elite.

Method

To test this argument we need two bodies of information, one bearing on events leading to the initiation of insurgency and the other dealing with the political environment shaping challenge outcomes. For the first, we have drawn on published accounts of the movements, filled in and corroborated by extensive interviews conducted with movement participants and informed observers. For the second, we have turned to newspaper sources to provide a picture of the societal response to the two challengers. By content coding the abstracts of news stories that dealt with farm labor issues printed in the *New York Times* over a twenty-seven-year period (1946-1972), we can determine the types of groups concerned with the question of farm labor, whether their actions favored the structural changes advocated by insurgents, the types of activities in which they were engaged and, finally, the pattern of interaction prevailing between these various groups during the course of the respective challenges. This way we have a systematic data base against which to test hypotheses bearing on movement-environment interaction.⁴

As with any data source, there are limits to the *Times* data. We cannot, for

example, use it to test hypotheses on the internal dynamics of mobilization. For this, we have gone to interviews and published sources. Nor, as Danzger's (1975) work has recently indicated, can we view the *Times* reportage as a complete picture of all insurgent activity and environmental responses to insurgency. Since it is a national newspaper, the *New York Times* will not provide us with day-to-day coverage, for example, of police repression in Delano, California. Nor can we count on the *Times* to reveal the hidden bargains and machinations that might underlie public positions and alliances.

We do not ask it to do so. What we are using the *Times* for is to construct a systematic, reliable index of the publicly visible political activities that formed the environment of each challenge. By comparing statistics drawn from this data base and relating these measures to differences in challenge outcome, we can see if our environmental thesis holds up.⁵

To see if the *New York Times* is a reliable source, we have compared the coverage given by the *Times* with that of two other newspapers, the *Chicago Tribune* for a more conservative picture and the *Los Angeles Times* for a more proximate source. After comparing the stories on farm labor carried by these three papers for one month (selected at the peak of activity for the three periods of analysis), we have concluded that the *New York Times* is basically a more complete version of the same "news." In the month selected from the first period (March, 1951), the *New York Times* covered seventeen events, only one of which was picked up by each of the other papers; no events in the "test" papers were missed by the *New York Times*. In the second period (April, 1958), the *New York Times* carried nine events, two of which the *Los Angeles Times* covered and none of which the *Tribune* covered; again the *New York Times* missed no events covered in the other papers. Only in the third period (October, 1968) did the *New York Times* miss an event, one involving a local

⁴ For a copy of the coding schedule used, contact the first author.

⁵ Inter-coder reliability was set at 90%; all items failing to meet this standard were excluded from the analysis.

organization that pressured the Los Angeles City Council to boycott grapes. This was reported in the *Los Angeles Times*. Of eight events covered by the *New York Times*, half appeared in the *Los Angeles Times* and none in the *Tribune*. In sum, if you want newspaper reportage on farm labor events, the *New York Times* is a more thorough source and reveals no clearly different bias than the other papers during one period of time, say, the NFLU challenge, than another, e.g., the UFW effort.

Finally, there is the question of whether news reportage, regardless of cross-validation with other news sources, is valid. Danzger (1975) has argued that news coverage is affected by editorial policy, and that systematic error creeps in because the geographic location of national wire service offices produces uneven reportage of relevant events. It is important to note that we code events, not news stories. The prominence given to stories by the editors of the *New York Times* is irrelevant, as are the evaluations of the events by news personnel. Additionally, our data set should be relatively immune to the main source of error identified by Danzger. Both insurgencies centered in the same locale. Assuming that the corrective mechanisms within the news agencies identified by Danzger were operative, time-series data should be less vulnerable to error than cross-sectional data. Also, we should note the limitations to Danzger's conclusions given his own data base. As Snyder and Kelly (1976) have demonstrated, news-based conflict data dealing with violence appear quite valid; more error exists in nonviolent protest data (employed in Danzger's test). Extending that distinction to our own data set, we can place more confidence in our measures of "concrete" activities than those for "symbolic" ones.

Basic Variables

Our analysis centers on the comparison of three time periods. The first, 1946–1955, spans the challenge of the National Farm Labor Union. Chartered to organize farm workers at the 1946 American Federation of Labor convention, the NFLU

launched a strike wave in the Central Valley of California that ended with the abortive Los Baños strike of 1952. The selection of 1955 as the end point of the period was somewhat arbitrary.

By comparison, the third period, 1965–1972, covers the sustained and successful challenge of the United Farm Workers. The 1965 Coachella and Delano strikes announced the UFW challenge; in 1970, after two years of nation-wide boycott efforts, the UFW brought table-grape growers to the bargaining table and began institutionalizing changes in the position of farm workers. (The Teamster entry in 1973 is not dealt with in this paper.)

During the period intervening between the two challenges, 1956–1964, important changes took place in the political system that set the stage for a successful challenge. In the absence of a major "push" from insurgents,⁶ issues pertaining to farm labor received a different treatment in the hands of established liberal organizations and government officials. We will argue that these years constituted a period of germination and elite reform that made possible the success of the late 1960s.

From the *New York Times Annual Index*, we have coded the types of groups involved, the direction and form of their activity and the issues involved. The groups are: (1) the farm worker associations and unions that represented farm worker insurgents; (2) federal, state and local governments; (3) the liberal organizations (religious, philanthropic, political action and "public interest" groups); (4) organized labor; (5) agribusiness associations, corporations and individual farmers, referred to collectively as the growers. Of these, the growers have the fewest events reported in the *Times*, probably because fewer of their activities are likely to constitute "notable" events in a journalistic sense—e.g., securing the services

⁶ The Agricultural Workers Organizing Committee (AFL-CIO) was chartered in 1959, but never posed a serious threat to growers (London and Anderson 1970: 46–78); the National Farm Worker Association was an independent community organization launched by Cesar Chavez in 1962 and entered the labor question in an offensive way only in 1965 (London and Anderson, 1970: 148–53).

of local police, hiring strikebreakers, rounding up support among legislators. Their views are generally presented quite effectively by the Department of Agriculture so they need do little public relations on their own.

The first step is to break down group activity by direction—into actions favorable, unfavorable, ambiguous, or not relevant to the interests of farm workers. (Only government had significant numbers of both favorable and unfavorable actions. All other groups were either wholly favorable or unfavorable. Government was also the only type with a large number of “ambiguous” or “not relevant” actions. These are excluded from the analysis; they do not depart in terms of issue or type of action from “directed” actions.) We then can estimate the balance of favorable/unfavorable actions in the political system during the course of each challenge, and chart the fluctuations in favorable and unfavorable actions by different types of groups (see Figures 1 and 2).

In addition to group and direction, we are concerned with the form of action adopted. We will distinguish between “symbolic” and “concrete” actions. Purely rhetorical acts which attempt to shape public opinion, e.g., speeches or hearings, are “symbolic”; actions that attempt to directly allocate control over material resources, e.g., court rulings and mass protest, fall under the rubric of “concrete.”

Issue is our final variable: (1) labor supply, which is largely centered around the importation of Mexican labor under the *bracero* and “green card” programs and which was the dominant issue during the NFLU challenge; (2) working and living conditions of farm workers, which dominated the remaining two periods; (3) unionization, i.e., the legality of collective bargaining in agriculture, a question which first appeared in significant measure only during the UFW challenge.

Two types of statistics drawn from this data set will be used. N's, percentages and percent differences set off the rough differences between the three periods of activity. To capture more precisely the divergent patterns of interaction taking

place between insurgents and among various groups in the polity, Pearson product-moment correlations are reported. The scores entering the analysis are counts of actions taken by different groups, on different issues, for conventional calendar years. High r 's are taken to indicate that considerable concomitant activity took place over the time period between relevant pairs of groups, e.g., insurgents and liberals; low r 's, the absence of concomitant activity. Bringing this to bear on the environmental thesis, differences in descriptive statistics and r 's for relevant pairings of groups will reveal any differences that existed in the societal response to the challenges.⁷

Period I: The NFLU Conflict (1946–1955)

The first period illustrates in classical terms the obstacles to a sustained and successful farm worker challenge. In addition to the structural constraints restricting farm worker activity, the political environment confronting the insurgents was unfavorable. Government officials at all levels and branches came into the conflict predominantly on the side of the growers, despite the mandate of agencies such as the Department of Labor or the Education and Labor Committees in Congress to protect the interests of deprived groups like farm workers. Though external support was decisive in launching the challenge, it was weak and frequently ill-focused, dealing with the consequences rather than the causes of farm worker grievances. When support was withdrawn, the challenge soon collapsed.

Chartered at the 1946 convention of the American Federation of Labor, the Na-

⁷ Contrary to most time-series analyses, controls for auto-correlation are inappropriate. The correlation analysis does not causally relate a dependent variable (e.g., level of insurgent activity) to a set of independent variables (e.g., level of liberal activity). Instead, it is designed to reveal whether significant differences exist between time periods in movement-environment interaction. These differences are then held to account for the divergent outcomes. Instead of asking, “Does liberal activity cause insurgency?” we are asking, “Did insurgent and liberal activities co-occur to a different extent during one challenge than another? Did this difference relate to different challenge outcomes?”

tional Farm Labor Union set out to accomplish what predecessors had been unable to do—successfully organize the farm workers of California's "industrialized" agriculture. The leadership cadre was experienced and resourceful. H. L. Mitchell, President of the NFLU, was former head of the Southern Tenant Farmers Union; the Director of Organizations, Henry Hasiwar, had been an effective organizer in several industrial union drives during the 1930s; Ernesto Galarza, who assumed prime responsibility for publicity efforts, had served as political liaison for Latin American unions and had a Ph.D. in economics from Columbia University.

Initially, the strategy was quite conventional: enlist as many workers as possible from a single employer, call a strike, demand wage increases and union recognition, and picket to keep "scabs" out of the fields. American Federation of Labor affiliates would then provide strike relief and political support to keep the picket line going. An occasional church or student group would furnish money and boost morale.

But the government-sponsored alien labor or *bracero* program provided growers with an effective strike-breaking weapon. According to provisions of the law, *braceros* were not to be employed except in instances of domestic labor shortage and *never* to be employed in fields where domestic workers had walked out on strike. Yet in the two major tests of union power, the DiGiorgio strike of 1948 and the Imperial Valley strike of 1951, the flood of *braceros* undermined the strike effort of domestic workers (London and Anderson, 1970; Galarza, 1970; Jenkins, 1975: ch. 3). In the Imperial strike, the NFLU used citizen's arrests to enforce statutes prohibiting employment of *braceros* in labor disputed areas. However, local courts ruled against the tactic and the Immigration Service refused to remove alien "scabs" from the fields (Galarza, 1970:78; Jenkins, 1975: ch. 4). Nor were affairs changed when the *bracero* administration was transferred to the U.S. Department of Labor in 1951. Domestic workers were pushed out of crops by *braceros*, and *braceros* reap-

peared in the Los Baños strike of 1952 to break the challenge (Galarza, 1970:79).

In response, the NFLU launched a two-pronged political challenge—a demand for termination of the *bracero* program and, to get around the problem of ineffective strikes, requests for organized labor's support of boycotts. Neither demand found a favorable audience. Lacking strong labor or liberal support, the demand for an end to the *bracero* traffic ended in minor reforms in the *bracero* administration (Galarza, 1970: ch. 4). As for the boycott, despite initial success, it collapsed when a court injunction was issued (improperly) on the grounds that the NFLU was covered by the "hot cargo" provisions of the Taft-Hartley Act. The National Labor Relations Board initially concurred and reversed its position over a year later. By then the Union's resources were exhausted and organized-labor support had long since collapsed (Galarza, 1970:73–92).

Figure 1 charts the level of favorable actions by selected groups, allowing us to gauge the societal response to insurgency. The curves delineating government, liberal, and farm worker activities move roughly in concert. (Organized labor, though, played little public role in this or the next period.) Checking these impressions, Table 1 reports Pearson r 's on relevant pairs of groups. Largely a reflection of the pressure campaign waged by the NFLU, the strongest correlation is between insurgents and favorable government activity (.63), concrete activities seemingly being more efficacious (.70 versus .49 for symbolic acts). R for insurgent/government activity drops only slightly when controls are introduced for liberal activity (.57), indicating that liberal activity was not necessary for this measure of official response.

The main issue for the period was labor supply. Looking at activities concerned with this issue, the correlation between insurgent and pro-farm worker government activities is high (.59); for the issue of living and working conditions, the relation disappears (–.08). The union attempted, through court actions, lobby efforts and public protest, to pressure gov-

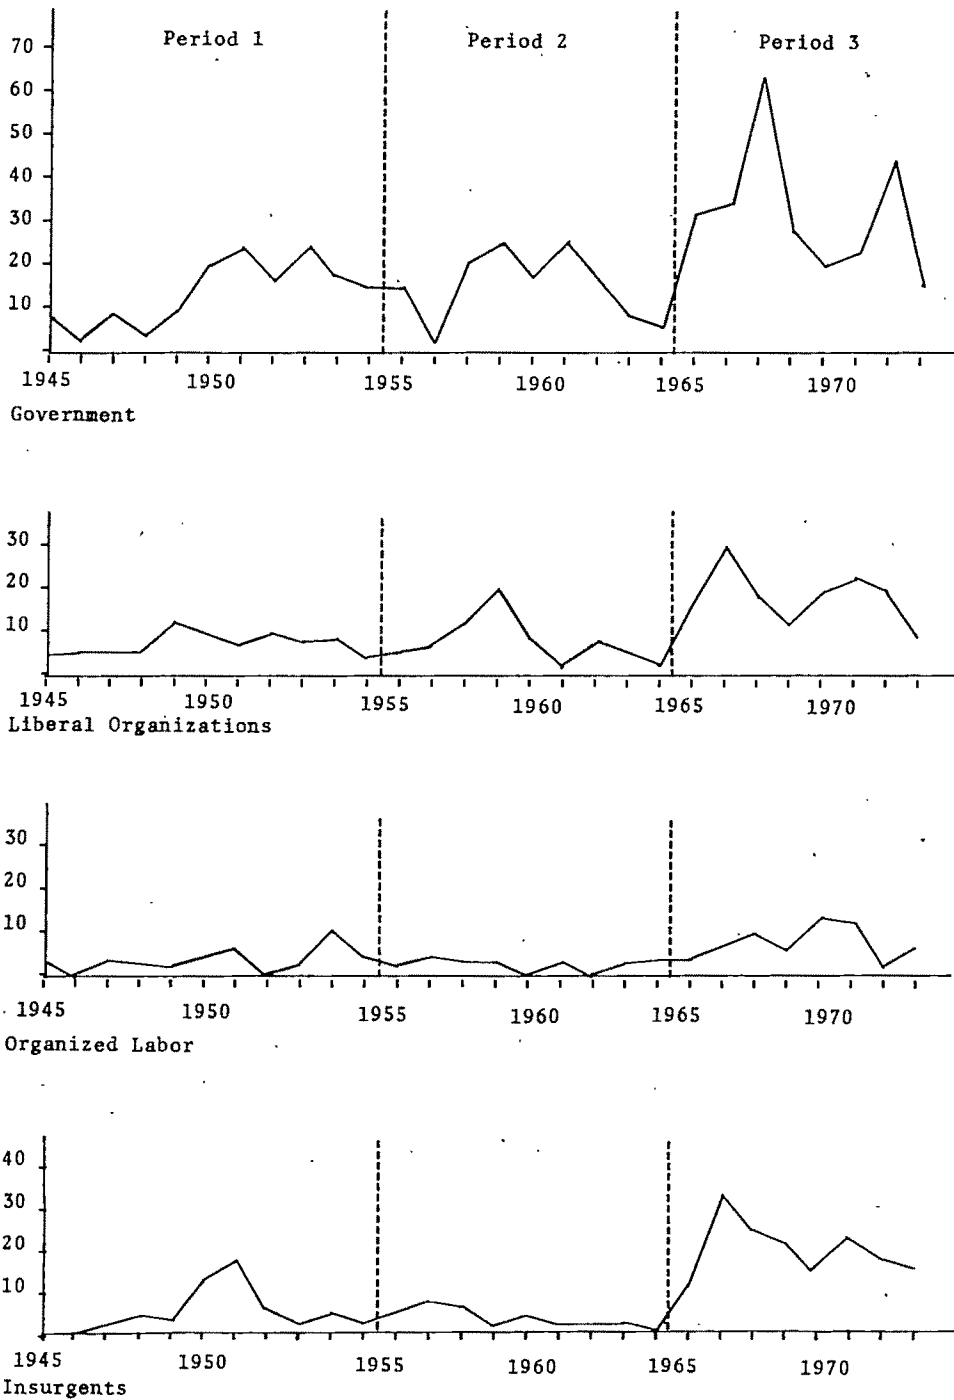

Figure 1. Actions Favorable to Insurgents

ernment to end the *bracero* program since it was so central to the control of the labor supply. The official response, however, was largely symbolic. Though govern-

ment tended to respond to concrete insurgency with favorable concrete actions, the majority of favorable governmental actions were actually symbolic (58%).

^b N for one group during this period was zero.

Nor did many of these concrete moves decisively aid the farm worker cause. Key actions, such as pulling strikebreaking *braceros* out of the fields, did not occur.

What, then, are we to make of the fact that 50% of reported governmental actions were coded as favorable to the interest of farm workers? Was government responding to the conflict between insurgents and growers in some even-handed "pluralist" way? Here it is necessary to recall that we are using news media reportage on a social problem and efforts to redress that problem. The news media will be more sensitive to efforts attempting to define or solve that problem than to efforts to maintain the *status quo*. Consequently, unfavorable actions by government and growers are underrepresented in our data. If only 50% of news-reported government actions can be coded as favorable, then the full universe of governmental activities should, in the balance, be more favorable to growers.

The strength of this assertion is borne out by information on actions favorable to growers. Figure 2 charts these actions for government and growers. The correlation between pro-grower government activities and grower activities is quite high (.75), actually stronger than the respective *r* for insurgents. In quantitative terms,

government was more responsive to agribusiness interests. Clearly, in critical instances, e.g., leaving *braceros* in struck fields, government policies favored growers over workers.

In addition to the predominantly unfavorable response of government, the NFLU failed to receive sustained, solid support from the liberal community. The major problem was the type of activities in which liberals engaged. When they acted, liberals consistently supported farm workers over growers but they rarely moved beyond symbolic proclamations. Only 24% of liberal actions during the period were concrete. By contrast, 38% during the UFW challenge were so. Even more indicative, though, is the modest level of the correlation between liberal and insurgent activity (.45). What concomitant activity did exist between these two groups involved only symbolic acts (.56 versus -.02 for concrete acts). Looking ahead, the respective *r*'s for the UFW challenge indicate a quite different liberal response. Overall, *r* was .62; for concrete actions, *r* was .83 and, for symbolic acts, .06. Where the UFW experienced consistent and concrete support, the NFLU found itself relatively isolated.

Though liberals did not rush to the side of the NFLU, they did play a role in the

Figure 2. Actions Favorable to Growers

pressure campaign. When controls are introduced for government activity on the relation between insurgents and liberals, the modestly positive relation turns negative ($-.10$). Insofar as liberals did act alongside insurgents, apparently it was in the presence of public officials. But there were problems even with this limited-scale liberal support. Liberals focused almost exclusively on the working and living conditions of farm workers. Following the lead of Progressive Party candidate Henry Wallace in 1948, several religious and "public interest" associations sponsored conferences and issued study reports publicizing deplorable camp conditions and child labor. In what might be considered a typical pattern of liberalism of the time, they were concerned with the plight of the workers rather than the fact of their powerlessness or the role of the *bracero* program in underwriting that powerlessness. It was a humanitarian, nonpolitical posture, easily dissipated by "red baiting" in Congressional investigations and "red scare" charges by growers and their political allies throughout the late 1940s and early 1950s. The two issues, poverty and the question of labor supply, were not to be linked by the liberal organizations until well into Period II.

Period II: Elite Reform and Realignment (1956-1964)

The late 1950s and the early 1960s, the second Eisenhower administration and the brief Kennedy period emerge from this and other studies in the larger project as a period of germination. Contrary to some interpretations, the remarkable insurgencies of the late 1960s did not originate with the Kennedy administration, but with developments that initially began to appear during Eisenhower's second term. Nor did the Kennedy years witness a dramatic escalation of insurgent activity. Indeed, in the case of farm workers, insurgency showed a decline (Figure 1). For our purposes, the two presidential administrations can be treated as a single period, one that witnessed important realignments and shifts in political resources in the national polity, culminating in a supportive environment for insurgent activity.

Farm worker insurgency during the reform period was at a low ebb. Actions by farm worker insurgents dropped from 16% to 11% of all pro-worker activity. In 1956-1957 the NFLU, now renamed the National Agricultural Workers Union (NAWU), secured a small grant from the

United Auto Workers, enabling it to hang on as a paper organization. Galarza, by then the only full-time cadre member, launched a publicity campaign to reveal maladministration and corruption within the *bracero* administration. Aside from a brief and ineffective organizing drive launched in 1959 by the Agricultural Workers Organizing Committee (AWOC), generating only one reported strike (in 1961), this was the sum of insurgent activity for the nine-year Period II (Figure 1). Growers remained publicly inactive and seemingly secure in their position, aroused only at renewal time for the *bracero* program to lobby bills through Congress. Until the insurgency of Period III began, growers retained a low profile in the *Times* (Figure 2).

With the direct adversaries largely retired from the public arena, affairs shifted into the hands of government and the liberals. Despite the absence of significant insurgency, the balance of forces in the national polity had begun to shift. Actions favorable to the interests of farm workers increased from 50% to 73%, remaining on the same plane (75%) throughout the following UFW period. Beginning during the last years of the Eisenhower administration, three interrelated developments brought about this new supportive envi-

ronment: (1) policy conflicts within the political elite that resulted in a more "balanced," neutral stance towards farm workers; (2) the formation of a reform coalition composed of liberal pressure groups and organized labor that, in the midst of elite divisions, was able to exercise greater political influence; (3) the erosion of the Congressional power-base of conservative rural interests, stemming immediately from reapportionment.

The concern of liberal pressure groups initially was focused on the need to improve housing and educational conditions of migrant workers. In 1956, the Democratic National Convention included a plank for increased welfare aid to migrants. The next year, the National Council of Churches, already involved in the early civil rights movement in the South, began a study of migrant camp conditions and child labor. In early 1958, the Council brought public pressure to bear on Secretary of Labor James Mitchell to enforce existing laws regarding migrant camps throughout the nation. In late 1958, several liberal pressure groups were joined by the AFL-CIO in attacking the *bracero* program, scoring administrative laxity, and arguing that federal labor policies were the origin of social problems. The two as yet unrelated issues—poverty and

labor policies—were now firmly linked in the public debate.

The fusion of these two issues was significant. Of course, economic conditions already had been linked with social deprivations in public parlance, but the concern of liberal groups in the past had been with inspection of housing, assurances of educational opportunity, and public health measures. To argue now that a public program of importing foreign labor perpetuated the list of conditions deplored by liberals was a substantial change. As later happened more generally with the New Left (cf. Perrow, 1972), the advocates of reform had begun to look at the source of problems in terms of a system.

About the same time, organized labor took a new interest in farm workers. In 1959, the AFL-CIO Executive Council abolished the NAWU and created the Agricultural Workers Organizing Committee (AWOC), headed by Norman Smith, a former UAW organizer. Despite strong financial backing, the AWOC produced little results. Concentrating on 4 A.M. "shake-ups" of day laborers, the AWOC managed to sponsor a number of "job actions" but only one major strike and little solid organization. Like the NFLU, the AWOC had to confront the problem of *braceros*. In the one reported strike, the Imperial Valley strike of February, 1961, the AWOC used violence to intimidate strikebreaking *braceros* and create an international incident over their presence. Officials quickly arrested the cadre, and the AWOC ceased to exist except on paper. Though the AWOC drive consumed over one million dollars of AFL-CIO funds, it produced neither contracts nor stable membership (London and Anderson, 1970:47–50, 77). Yet, and this indicates the shift, this type of financial support had never before been offered by organized labor.

The final element in the formation of a supportive environment was a shift in governmental actions. Actions favorable to farm workers increased from the unfavorable 50% prevailing during Period I to a more "balanced" 68% of all governmental actions. Of these, the portion coded "concrete," and therefore more likely to have impact, increased from 40%

in Period I to 65%. Indicative of the change taking place in official views, the focus of governmental attentions shifted from the labor supply issue (56% of favorable actions during Period I) to the question of farm workers' living and working conditions (73% during Period II).

The change in official actions stemmed, in part, from internal conflicts within the national political elite. Secretary of Labor James Mitchell was a surprise Eisenhower appointee from the Eastern wing of the Republican Party, a former labor consultant for New York department stores and a future protege of Nelson Rockefeller. Mitchell took the Department of Labor in a more pro-union direction than was thought possible, at the time becoming a "strong man" in the cabinet because of his success in mollifying unions.⁸ In 1958, an open fight between the Taft and Eastern wings of the Republican Party developed, with the conservatives favoring a national "right-to-work" law. Mitchell, as an advocate of unionism and apparently jockeying for position for the Republican Vice-Presidential nomination, became a figure of elite reform within Republican circles.

A second factor contributing to the shift in official actions was the pressure campaign launched by the reform coalition. The effects of the campaign can be captured, in part, from the *Times* data. Though the correlation between liberal activity and government activity favorable to farm workers is modest (.50), it is considerably higher than during the other periods (.33 for the first and .04 for the third) and it is independent of insurgent activity.

Tangible effects of the pressure campaign appeared almost immediately. In 1957, under pressure from the liberal reform coalition, the Department of Labor under Mitchell's guidance carried out an internal review of farm labor policies. The upshot was a series of executive orders to tighten up enforcement of regulations covering migrant camps (Craig, 1971: 151–5). When the economic recession of 1958–1959 arrived, sensitivity within the

⁸ *New York Times*, October 5, 1958, VI; 9: 2; October 20, 1964: 37:1.

Administration to rising unemployment levels increased. In response, Mitchell vowed to enforce more fully the 1951 statutes requiring farm employment to be offered to domestic workers prior to importation of *braceros*. Growers, long accustomed to having their *bracero* requests met automatically, rebelled when asked to provide more justification (Jacobs, 1963: 183-4). In February, 1959, Mitchell took an even stronger step, joining the liberal reformers in support of legislation to extend minimum-wage laws to agriculture and to impose new restrictions on the use of *braceros*.

The following year, the division within the Eisenhower Administration opened up into a full-scale, cabinet-level battle over renewal of the *bracero* program. The Farm Bureau and the state grower associations engaged that other administration "strong man," Secretary of Agriculture Ezra Taft Benson, to defend the program. In testimony before the House Committee on Agriculture, the White House took a neutral stance; Benson defended the program, while Mitchell argued that the program exerted demonstrable adverse effects upon domestic workers and should be abolished (Craig, 1971: 156-61). Into this breach in the political elite stepped the liberal-labor support coalition. At the same time, the House Committee on Public Welfare opened hearings on health and camp conditions, giving the Cotton Council and the Meatcutters Union a chance to air opposing views.

Initially, the reform effort failed. In March, 1960, Secretary Mitchell withdrew his program, resolving the dispute on the cabinet level. The next month, agribusiness pushed a two-year renewal of the *bracero* program through Congress. But, for the first time, the issue had been debated seriously and a loose coalition of liberal pressure groups (e.g., National Council of Churches, National Advisory Committee of Farm Labor, NAACP) and organized labor had formed. Though the eventual termination of the *bracero* program did not undermine growers' ability to break strikes (there were other substitutes, e.g., "green card" commuters, illegal aliens), the fight against the program

did refocus the concern of liberals and organized labor on the structural problem of farm worker powerlessness.

The reform coalition sustained the campaign over the next three years. In 1960, the Democratic platform condemned the *bracero* program. Once in office, the New Frontiersmen, though demanding no important statutory changes, did vow to enforce fully the laws restricting *bracero* use (Craig, 1971: 174). By renewal time in 1963, the Kennedy Administration was in the pursuit of a public issue ("poverty") and courting minority-group votes. For the first time, the White House went formally on record against the program. Only at the last minute was a pressure campaign, mounted by Governor Pat Brown of California and the Department of State, responding to Mexican diplomatic pressure, able to save the program temporarily. Amid promises from Congressional farm bloc leaders that this was the last time the program would be renewed, a one-year extension was granted.

In addition to the efforts of the reform coalition, which played a critical role in other reforms of the same period, and the new elite-level neutrality, the fall of the *bracero* program stemmed from the narrowing power base of the Congressional farm bloc. Congressional reapportionment had visibly shaken the conservative farm bloc leaders. Searching for items in the farm program that could be scuttled without damaging the main planks, the farm bloc leaders fixed on the *bracero* program. The mechanization of the Texas cotton harvest had left California growers of specialty crops the main *bracero* users. When the test came, *bracero* users, as a narrow, special interest, could be sacrificed to keep the main planks of the farm program intact (Hawley, 1966).

Period II, then, emerges from this analysis as a period of reform and political realignment that dramatically altered the prospective fortunes of insurgents. Reforms, stemming from elite-level conflicts and a pressure campaign conducted by liberal public-interest organizations and organized labor, came about in the virtual absence of activity by farm worker insurgents. The activism of several key liberal organizations depended, in turn, upon

broad economic trends, especially the growth of middle-class disposable income that might be invested in worthy causes (McCarthy and Zald, 1973). Insurgents did not stimulate these changes in the national polity. Rather, they were to prove the beneficiaries and, if anything, were stimulated by them.

Period III: The UFW Success (1965–1972)

During the NFLU period, the number of insurgent actions reported totalled 44. Most of these were symbolic in character, only 27% being concrete. Insurgency was brief, concentrated in a four-year period (1948–1951). However, in the third period, insurgency became sustained. Insurgent actions reached a new peak and remained at a high level throughout the period. A total of 143 actions conducted by farm worker insurgents were recorded. Significantly, 71% of these were concrete in character. By the end of the period, the success of the United Farm Workers was unmistakable. Over a hundred contracts had been signed; wages had been raised by almost a third; union hiring halls were in operation in every major agricultural area in California; farm workers, acting through ranch committees set up under each contract, were exercising a new set of powers.

The key to this dramatic success was the altered political environment within which the challenge operated. Though the potential for mobilizing a social base was slightly more favorable than before, the UFW never was able to launch effective strikes. Though the UFW cadre was experienced and talented, there is little reason to believe that they were markedly more so than the NFLU leadership; neither did the tactics of the challenge differ. The boycotts that secured success for the UFW also had been tried by the NFLU, but with quite different results. What had changed was the political environment—the liberal community now was willing to provide sustained, massive support for insurgency; the political elite had adopted a neutral stance toward farm workers.

As before, external support played a critical role in launching the challenge.

The initial base for the United Farm Workers was Cesar Chavez's National Farm Workers Association (NFWA) and remnants of the AWOC still receiving some support from the AFL-CIO.⁹ During the 1950s, Chavez had been director of the Community Service Organization, an Alinsky-styled urban community-organization with strong ties to civil rights groups, liberal churches and foundations. Frustrated by the refusal of the CSO Board of Directors to move beyond issues salient to upwardly-mobile urban Mexican-Americans, Chavez resigned his post in the winter of 1961 and set out to organize a community organization among farm workers in the Central Valley of California. Drawing on his liberal contacts, Chavez was able to secure the backing of several liberal organizations which had developed a new concern with poverty and the problems of minority groups. The main sponsor was the California Migrant Ministry, a domestic mission of the National Council of Churches servicing migrant farm workers. During the late 1950s, the Migrant Ministry followed the prevailing policy change within the National Council, substituting community organization and social action programs for traditional evangelical ones (Pratt, 1972). By 1964, the Migrant Ministry had teamed up with Chavez, merging its own community organization (the FWO) with the NFWA and sponsoring the Chavez-directed effort.¹⁰

By summer, 1965, NFWA had over 500 active members and began shifting directions, expanding beyond economic benefit programs (e.g., a credit union, cooperative buying, etc.) to unionization. Several small "job actions" were sponsored. Operating nearby, the remaining active group of the AWOC, several Filipino

⁹ For a detailed discussion, see Jenkins (1975: chs. 7–8).

¹⁰ There was also a brief challenge launched in 1965 among black tenant farmers in the Mississippi Delta region (the Mississippi Freedom Labor Union). The dynamics of that challenge are virtually identical to the UFW—sponsorship by liberal churches, labor union, etc. (for a history, see Hilton, 1969). Given the low event-count for this challenge, though, the statistics reported pertain to the UFW.

work-crews, hoped to take advantage of grower uncertainty generated by termination of the *bracero* program. The AWOC launched a series of wage strikes, first in the Coachella Valley and then in the Delano-Arvin area of the San Joaquin Valley. With the AWOC out on strike, Chavez pressed the NFWA for a strike vote. On Mexican Independence Day, September 16th, the NFWA joined the picket lines (Chavez, 1966; Dunne, 1967; London and Anderson, 1970).

Though dramatic, the strike soon collapsed. Growers refused to meet with union representatives; a sufficient number of workers crossed the picket lines to prevent a major harvest loss. Over the next six years, the same pattern recurred—a dramatic strike holding for a week, grower intransigence, police intimidation, gradual replacement of the work force by playing upon ethnic rivalries and recruiting illegal aliens (cf. Dunne, 1967; London and Anderson, 1970; Matthiessen, 1969; Kushner, 1975; Taylor, 1975). What proved different from the NFLU experience was the ability of the insurgents, acting in the new political environment, to secure outside support.

Political protest was the mechanism through which much of this support was garnered. By dramatic actions designed to capture the attention of a sympathetic public and highlight the "justice" of their cause, insurgents were able to sustain the movement organization and exercise sufficient indirect leverage against growers to secure contracts. The UFW's use of protest tactics departed from that of rent strikers analyzed by Lipsky (1968; 1970). Though the basic mechanism was the same (namely, securing the sympathy of third parties to the conflict so that they would use their superior resources to intervene in support of the powerless), the commitments of supporting organizations and the uses to which outside support was put differed. Lipsky found that protest provided unreliable resources, that the news media and sympathetic public might ignore protestors' demands (cf. Goldenberg, 1975) and that, even when attentive, they often were easily satisfied with symbolic palliatives. Though the UFW experienced these problems, the presence of

sustained sponsorship on the part of the Migrant Ministry and organized labor guaranteed a stable resource base.

Nor were the uses of protest-acquired resources the same. Lipsky's rent-strikers sought liberal pressure on public officials. For the UFW, protest actions were used to secure contributions and, in the form of a boycott, to exercise power against growers. Marches, symbolic arrests of clergy, and public speeches captured public attention; contributions from labor unions, theater showings and "radical chic" cocktail parties with proceeds to "*La Causa*" supplemented the budget provided by sponsors and membership dues.

Given the failure of strike actions, a successful outcome required indirect means of exercising power against growers. Sympathetic liberal organizations (e.g., churches, universities, etc.) refused to purchase "scab" grapes. More important, though, major grocery chains were pressured into refusing to handle "scab" products. To exercise that pressure, a combination of external resources had to be mobilized. Students had to contribute time to picketing grocery stores and shipping terminals; Catholic churches and labor unions had to donate office space for boycott houses; Railway Union members had to identify "scab" shipments for boycott pickets; Teamsters had to refuse to handle "hot cargo"; Butchers' union members had to call sympathy strikes when grocery managers continued to stock "scab" products; political candidates and elected officials had to endorse the boycott. The effectiveness of the boycott depended little upon the resources of mobilized farm workers; instead, they became a political symbol. It was the massive outpouring of support, especially from liberals and organized labor, that made the boycott effective and, thereby, forced growers to the bargaining table.

The strength of liberal-labor support for the UFW is indicated by the high level of concomitant activity between insurgents and their supporters. While the correlation of insurgent and liberal activities was modest in Period I (.45), it was strong during the third period (.62). More impor-

tant, liberals were far more concrete in their support for insurgents. In the first period, concomitant activities were almost wholly symbolic (.56 versus .02 for concrete activities); during the UFW challenge, it was concrete activities (.81 versus .06 for symbolic activities). Nor do statistical controls for governmental actions favorable to farm workers reduce the correlation ($r = .64$). Given the fact that liberal activities rarely occurred jointly with pro-worker government activities ($r = .04$), it is clear that liberals directed their efforts toward supporting insurgents rather than pressuring government.¹¹

The more "balanced," neutral posture of government that was the product of the reform period continued. Sixty-nine percent of all official actions were favorable to farm workers (as against 50% and 68% in Periods I and II). Concretely, this meant that court rulings no longer routinely went against insurgents; federal poverty programs helped to "loosen" small town politics; hearings by the U.S. Civil Rights Commission and Congressional committees publicized "injustices" against farm workers; welfare legislation gave farm workers more economic security and afforded insurgents a legal basis to contest grower employment practices. National politicians, such as Senators Kennedy and McGovern, lent their resources to the cause.

The most striking changes in official actions took place on the federal level. Actions favorable to farm workers rose from 46% of federal level activity in the first period, to 63% in the second and 74% in the third. State and local government, more under the control of growers (cf. McConnell, 1953:177; Berger, 1971), followed a different pattern. In Period I, when growers had opposition only from insurgents, only 26% of official actions were judged favorable to workers. In Period II, when farm workers were ac-

quiescent but the liberal-labor coalition was experiencing growing influence in national politics, 67% were favorable, slightly more than on the federal level. But when insurgency reappeared in Period III, the percent favorable dropped to 45%, far lower than the federal level. Government divided on the question, federal actions tending to be neutral, if not supportive, of insurgents while state actions, still under grower dominance, continued to oppose insurgents.

Significantly little of the pro-worker trend in governmental actions during the UFW period is associated with either insurgent or liberal activities. For insurgent and favorable government actions, r is low (.26 versus .63 during the NFLU period); the correlation between liberal organizations and favorable government actions drops to the lowest point in the study (.04 versus .33 and .50 for Periods I and II, respectively). Only organized labor appeared to be performing a pressure function. There is a modest correlation between symbolic activities by organized labor and government (.46), largely centering around the legitimacy of unionism in agriculture ($r = .35$). Official positions had already undergone important changes during the reform period. The termination of the *bracero* program had left government in a neutralized position. No longer a key player in the conflict, but still under the influence of the reform policies, government preserved its neutral stance despite less visible pressure from any of the partisans.¹²

There was, of course, opposition on the part of growers and allied governmental actors. There were numerous instances of police harassment, large-scale purchases of boycotted products by the Department of Defense, and outspoken opposition

¹¹ Despite the fact that help from organized labor was critical to the boycott's success, our correlations hardly document the point. In the NFLU challenge, r was .08; in the UFW period, .16. This relation is weaker than that for liberal pressure groups, we would argue, because much of the supportive labor action was "local" in character and often went unreported in the *Times*.

¹² Corroborating this interpretation, the correlation between insurgent/liberal actions and pro-worker government actions is considerably stronger (.74 and .58, respectively) once insurgent and liberal actions are lagged by one year. As a roughly neutral participant, government followed along a year behind the chief partisans, though not responding directly to pressure as before. Though not conclusive, the fact that this was the only instance in the study in which time-lags produced marked increases in r 's lends the interpretation some plausibility.

from Governor Reagan and President Nixon.

However, growers had lost their entrenched political position. Public officials no longer acted so consistently to enhance grower interests and to contain the challenge. An indication of the sharpness of the displacement of growers is given by the levels of concomitance between grower actions and pro-grower governmental actions. In Period I, r for grower-government activity was .75; in Period II, .62. But, during the UFW challenge, the correlation dropped to a negligible .05. By the time the United Farm Workers struck in 1965, agricultural employers were no longer able to rely upon government, especially at the federal level, to be fully responsive to their interest in blocking unionization.

Conclusion

The critical factor separating the National Farm Labor Union failure from the United Farm Worker success was the societal response to insurgent demands. In most respects, the challenges were strikingly similar. In both instances, the leadership cadre came from outside the farm worker community; external sponsorship played a critical role in launching both insurgent organizations; both movements confronted similar obstacles to mobilizing a social base and mounting effective strikes; both resorted to political protest and boycotts. What produced the sharp difference in outcome was the difference in political environment encountered. The NFLU received token contributions, vacillating support for its boycott and confronted major acts of resistance by public authorities. In contrast, the UFW received massive contributions, sustained support for its boycotts and encountered a more "balanced," neutral official response.

The dramatic turnabout in the political environment originated in economic trends and political realignments that took place quite independent of any "push" from insurgents. During the reform period, conflicts erupted within the political elite over policies pertaining to farm workers. Elite divisions provided the

opening for reform measures then being pressed by a newly active coalition of established liberal and labor organizations. Though the reforms did not directly effect success, the process entailed by reform did result in a new political environment, one which made a successful challenge possible.

If this analysis is correct, then several assumptions found in the classic literature are misleading. Rather than focusing on fluctuations in discontent to account for the emergence of insurgency, it seems more fruitful to assume that grievances are relatively constant and pervasive. Especially for deprived groups, lack of collective resources and controls exercised by superiors—not the absence of discontent—account for the relative infrequency of organized demands for change. For several of the movements of the 1960s, it was the interjection of resources from outside, not sharp increases in discontent, that led to insurgent efforts.

Nor does the political process centered around insurgency conform to the rules of a pluralist game. The American polity had not been uniformly permeable to all groups with significant grievances (cf. Gamson, 1975). Government does not act as a neutral agent, serving as umpire over the group contest. Public agencies and officials have interests of their own to protect; interests that often bring them into close alignment with well-organized private-interest groups. When insurgency arises threatening these private interests, public officials react by helping to contain insurgency and preserve the *status quo*. But if an opposing coalition of established organizations decides to sponsor an insurgent challenge, the normal bias in public policy can be checked. Sponsors then serve as protectors, insuring that the political elite remains neutral to the challenge.

The implications for other challenges are rather striking. If the support of the liberal community is necessary for the success of a challenge by a deprived group, then the liberal community is, in effect, able to determine the cutting edge for viable changes that conform to the interests of those groups still excluded from American politics. Moreover, there is the possibility of abandonment. Since

liberal support can fade and political elites shift their stance, as has happened to the UFW since 1972, even the gains of the past may be endangered. The prospects for future insurgency, by this account, are dim. Until another major realignment takes place in American politics, we should not expect to see successful attempts to extend political citizenship to the excluded.

SOCIAL CHANGE AND THE FAMILY: LOS ANGELES, CALIFORNIA, 1850-1870*

BARBARA LASLETT

University of Southern California

American Sociological Review 1977, Vol. 42 (April):268-291

Using Marx's description of "the so-called primitive accumulation" which he associates with the development of capitalism in the West, a theoretical formulation is presented which explores the impact on the family of changes in the individual's access to actual and potential wealth. A multivariate analysis, based on the individual census schedules for the city of Los Angeles in 1850 and 1870, is used to explore the changing relationships between economic, demographic and other structural variables on household structure. The findings suggest that a dynamic, Marxian model can help explain the effects of social change on the family.

Theories of social change in relation to the family have received considerable attention from social scientists. (see, for instance, Parsons, 1959; Linton, 1959; Goode, 1963; Skolnick, 1973: ch. 3; Hareven, 1976). Until recently, however, historical research has been lacking which

would permit an empirical assessment of these theories. This paper, which presents a macro-structural analysis of household organization in a developing nineteenth-century American city, hopes to make a contribution to this assessment and to suggest a new conceptual framework for understanding the family in historical perspective.

Studies of social change can attend not only to outcomes—such as variations in the distribution of family types in different time periods—but also to the processes by which these changes came about. The longitudinal design of the research discussed in this paper provides an opportunity to empirically assess process as well as results. The conclusions of studies of

* This investigation was supported by Biomedical Sciences Support Grant RR07012-08 from the Division of Research Resources, Bureau of Health Professions Education and Manpower Training, National Institute of Health. Special thanks are given to James E. Smith for his work on the larger project of which this paper is one part. The author would also like to thank Edna Bonacich, David Heer, Carol Warren, Lutz Berkner and Robert Brenner for critical readings of this paper, a version of which was presented at the 1976 meetings of the American Sociological Association, New York.

process, however, are likely to be varied, in part because of historical and structural differences between units of analysis. Brenner (1976), for instance, presents a brilliant analysis which traces variations in the transition to capitalism in different European societies. The findings of a study of social change in Los Angeles, whose history differs from other (and older) American communities, can be compared to the ways in which other social units experienced change historically. The conceptualization developed in this paper suggests a model for understanding variations in the processes of social change as they relate to the family. A brief description of Los Angeles in the nineteenth century provides the historical context within which this analysis can be understood.

California in the Nineteenth Century

California, which had been ceded by Mexico in 1848, became part of the United States in 1850. At that time, the main economic activity in the southern part of the state was cattle ranching. Although individual ownership of land had been restricted during the period of Spanish domination, under Mexican rule this policy was reversed and private ownership was encouraged. By 1846, nearly all of Southern California's arable and pasture land was owned by private proprietors with holdings running from less than 100 to more than a million acres (Fogelson, 1967:7-8).

Social organization prior to 1850 centered around the life of the ranchos whose production was geared primarily to its own consumption needs. Given a mild climate, the richness of the natural environment, a virtual absence of taxation and an almost cost-free labor force of indigenous Indians, domestic units were able to achieve considerable economic and social autonomy. (see Fogelson, 1967; Cleland, 1969; McWilliams, 1946).

This situation did not last long after the American takeover. By 1870, although the area was still primarily agricultural, considerable land subdivision and diversification of both occupations and economic activities had taken place. Sheep farming

assumed some of the emphasis which had been given previously to cattle and vineyards; and citrus fruit, as well as other types of agricultural produce, began to make a greater mark on the economy than they had done previously.

Commerce and manufacturing also developed during this period. The census of 1850 listed only one product of industry in the area: 42,280 loaves of bread valued at \$8,560 (Newmark and Newmark, 1929:21). By 1870, the value of the products of manufacturing in the county had risen to \$725,036 (U.S. Census Office, 1872:814).

Population growth was also a central feature of the changes that were affecting the city during this period: the population of Los Angeles increased from 1,610 in 1850 to 5,728 in 1870 (Fogelson, 1967:21), and the number of households grew from less than 300 in 1850 to 1,949 in 1870. Migration was a significant factor in the magnitude and rapidity of this population growth. Although the Civil War was a major event on the national scene at this time, its impact in the western states was less than in other areas of the country. An event of greater importance for Los Angeles than the Civil War was the establishment of rail connections to San Francisco and New Orleans, facilitating migration into the area. These factors led to greater ethnic and occupational diversity within the city and an increasing variety in its social institutions.

Within the twenty years under consideration here, Los Angeles developed from an isolated, self-sustaining and largely barter economy to a trade-dependent, money system. As Fogelson (1967:14) describes it, the city was shifting from "self-sufficient agriculture to market agriculture—from varied production for immediate consumption to specialized production for distant consumers."

Social Change and Family Structure

Marx's discussion of "the so-called primitive accumulation" suggests some useful guidelines through which to understand the changes occurring in Los Angeles during the period under investigation. According to Marx (1967:714):

The capitalist system pre-supposes the complete separation of the labourers from all property in the means by which they can realise their labour. . . . The process, therefore, that clears the way for the capitalist system, can be none other than the process which takes away from the labourer the possession of his means of production; a process that transforms, on the one hand, the social means of subsistence and of production into capital, on the other, the immediate producers into wage-labourers. The so-called primitive accumulation, therefore, is nothing else than the historical process of divorcing the producer from the means of production.

This framework draws attention to two interrelated structural changes, which began in Los Angeles, particularly after 1850: (1) changes in the producer's relationship to the economic structure, i.e., their transformation from possessors of the means of production and subsistence into wage workers and (2) consequent changes in the macro-economic structure of social organization, i.e., the transformation of the means of production and subsistence into "capital." From a Marxist perspective, these changes created the preconditions for the development of capitalism in Los Angeles and the eventual incorporation of Southern California into a national (and ultimately international) economic system. The formulation developed here will explore the implications of these structural transformations for understanding changes in the family which the empirical analysis documents.

The decline in proprietorship and increase in the proportion of wage workers in the twentieth century has been noted by many sociological observers. (for instance, Blau and Duncan, 1967). The consequences of these changes in economic organization for the political order and stratification system have been widely discussed. Their impact upon the family, however, has received less attention. Although some scholars have discussed in general and/or theoretical terms the effects of "industrialization" (Parsons, 1959; Linton, 1959), "modernization" (Goode, 1963) and the development of capitalism (Zaretsky, 1973; Shorter, 1975) upon the family, detailed empirical studies

have been rarer.¹ The empirical analysis to follow, however, provides an opportunity to investigate the utility of Marx's conception of "the so-called primitive accumulation" for understanding family organization in nineteenth-century Los Angeles. This will be done by focusing on the dynamics and effects of variation in individual accumulation of wealth as a means of interpreting changes in household structure over time.

It needs to be emphasized that the model presented here does not focus merely on the effects of the changing distribution of individual wealth on the family, but interprets changes in this distribution in the context of changes in the macrosocial structure associated, in Marx's view, with the development of capitalism. While evidence will not be available in this analysis to fully test the formulation presented, a Marxian perspective provides a basis for understanding the process and effects of social change in relation to the family which seems to account, at least in part, for changes in the family that occurred in nineteenth-century Los Angeles.

Two types of individual wealth—actual and potential—are a central focus of the formulation developed here. The unequal distribution of material economic assets—such as real estate—creates variation in the actual wealth which individuals possess. Variation also may occur in the potential for the accumulation of wealth through such things as differential access to the socioeconomic rewards of upward mobility. The data used in this analysis provide three individual-level measures of economic resources: occupation, real estate ownership and personal estate. Real and personal estate will be interpreted as

¹ Few full-length empirical monographs of the family in historical perspective in the early stages of industrialization are available. Some exceptions are Sennett (1970), Anderson (1971) and Katz (1975). Other recent books on the subject, such as Demos (1970) and Greven (1970) deal with the colonial period of American history. Farber (1972) covers a transitional period between the colonial era and the mid-nineteenth century. Hall (1974) looks at the effects of changing business practices on the family between 1700 and 1900.

indicators of actual wealth, and occupation will be used as an indicator of potential wealth. While the meaning of real and personal estate to measure variation in actual wealth is clear, the use of occupation to measure potential wealth requires some elaboration.

Occupational groups vary in terms of the range of opportunities available to their members. For instance, unskilled laborers may have low potential for accumulation from their wages and a limited range of opportunities for mobility while professionals may have higher potential accumulation from earnings but also have a limited range of mobility outcomes, since most movement through the occupational hierarchy is over short distances. (See Blau and Duncan, 1967, for the twentieth-century occupations; Thernstrom, 1964 and Katz, 1975, provide findings which suggest a similar pattern for the nineteenth century.) However, other occupations—proprietors and skilled craftsmen appear to have fallen into this category in the nineteenth century—may have had relatively high (although not equal) potential for earnings but greater variation in the range of mobility outcomes associated with their labor force participation.² Further research is necessary to empirically assess these differences between occupational groups. Conceptually, however, the formulation developed here uses these sources of variation in an individual's access to the accumulation of wealth to understand changes in household and family structure over time.

Both actual and potential accumulation have a temporal dimension which is important for understanding processes of change both through history and over the individual life cycle: prior accumulation can, over time, be reduced, maintained or increased and the potential for accumulation may or may not be realized. The suc-

cess of converting the potential for accumulation into actuality (as well as success in maintaining or increasing resources already accumulated) is likely to depend both on attributes of the individual and changes in the macro-social structure which defines the range of opportunities available to the individual.

Historical research has shown that household and family structure is related to individual levels of actual accumulation. Berkner (1972) and B. Laslett (1975) found, for instance, that extended family living was positively related to the wealth of the household head in eighteenth-century Austria and nineteenth-century Los Angeles, respectively. The effect of an individual's potential for accumulation on household structure is more likely to be felt through the burden of dependency, i.e., through the demands which different types of family (and/or household) composition impose upon resources.³ Households with higher burdens of dependency relative to their resources are less likely to accumulate wealth than households with lower dependency ratios. B. Laslett's (1975) analysis of household structure in Los Angeles in 1850 shows that the burden of dependency varies by household type, with the highest burden being found among simple family households, i.e., those which were nuclear in their kinship organization and did not include unrelated persons (such as boarders) as members of the co-resident domestic group.

There are, then, both theoretical and empirical reasons to expect an individual's actual and/or potential for accumulation to explain, at least in part, variation in household structure cross-sectionally and over time in the following ways. (1) Individuals with high actual as well as potential accumulation can afford household organizations with a relatively greater

² See Blau and Duncan (1967: ch. 2) for a discussion of such differences among twentieth-century American occupations. Slosser (forthcoming) is working on a study of intragenerational mobility in late nineteenth-century Los Angeles which will provide data on the mobility potential of different occupational groups.

³ The traditional functionalist paradigm also discusses dependency in relation to social change and the family. From that perspective, however, attention is given to the supposedly greater ease of mobility which nuclear, compared to extended, families permit. It does not discuss the ratio of dependents to resources, which is another feature of the same attribute.

burden of dependency.⁴ (2) The type of co-resident domestic group which would provide persons with high potential for accumulation but low levels of actual wealth with the greatest opportunity to transform their potential into actuality would be those in which there was a low dependency ratio. This could be achieved by postponing either marriage or child bearing or by limiting fertility. (3) The household structure of persons with high actual and low potential accumulation would, over time, be expected to reflect attempts to lower their burden of dependency. (4) Individuals with low actual and low potential accumulation might be more likely to view the benefits of family life in terms other than those having to do with the accumulation of wealth.

An additional elaboration is required in order to discuss life-cycle variation in household organization. To suggest that some social categories have greater potential for accumulation than others is not to maintain that all members of that category actualize their potential. Participation in a household or family structure meant to maximize accumulation does not ensure that accumulation will occur. There should, therefore, be life-cycle variation in household structure which reflects changes in the types of wealth the individual possesses—with potential being a more powerful predictor early in an individual's life and actual accumulation being a more powerful predictor later in the life cycle.

If this formulation is correct, the distinction between actual and potential accumulation provides one basis for a dynamic interpretation of the relationships between individual attributes and household organization. The effect of the social changes at the macro-structural level which Marx identified—the separation of the means of production and subsistence from the direct producers and the consequent emergence of “capital” (and capitalism) on the one hand and wage workers on the other—should affect the distribution and direction of these rela-

tionships over time through their impact on the range of opportunities which structure the individual's access to accumulation.

Methodology

The data for this analysis were taken from the individual census schedules for the City of Los Angeles in 1850 and 1870.⁵ Some of the problems involved in working with these data have been discussed elsewhere (B. Laslett, 1975). They will be reviewed briefly below, followed by additional issues relevant to the present analysis.

One of the features of studying family structure through census records is that the household, rather than the family, is the unit of analysis. Family structure as measured here reflects relationships among persons linked by conjugal or parent-child ties who shared a given residence on the date of census enumeration. It excludes persons who may be part of the same kinship group but who live in other households. This limitation could provide findings which truncate the actual kinship linkages among families who lived in Los Angeles during the period under investigation.

The most serious problem involved in using the U.S. federal census schedules to study family structure prior to 1880 is the absence of information on intra-household relationships through which the household structure variable is constructed. It was necessary, therefore, to infer these relationships through a series of coding rules based on surname identification and the instructions circulated to the federal census enumerators which specified the way in which different types of household members were to be listed (see Wright, 1900; B. Laslett, 1975). Persons with the same surname as the household head were coded as kin, and the order in which they were listed as well as sex and age were used to infer the specific nature of the relationship. Persons with different sur-

⁴ In 1850, extended family households were found to have a dependency ratio only slightly lower than simple family households (see B. Laslett, 1975).

⁵ The 1850 data were available in Newmark and Newmark (1929). The 1870 data were derived from microfilm of the original census schedules obtained from the National Archives in Washington, D.C.

names were coded as unrelated to the household head.⁶

This coding system is admittedly crude and, in particular, may underestimate the presence of kin related along the female line. In view of the limitations of the data, no coding system which eliminates this deficiency could be devised. The 1850 and 1870 schedules were coded in the same way and, while there may be error in inferring some intra-household relationships, the results are comparable.

For 1850, the entire population of households within the city was included in the analysis. The population had grown sufficiently large by 1870 so that sampling was appropriate and approximately 1,000 ($N=1,003$) were randomly chosen from the total number ($N=1,949$) listed on the census schedules. A final N of 929 from this sample forms the basis of the 1870 analysis.⁷

All intra-household relationships and household types in the 1850 data received a reliability score which indicates the degree of agreement between two independent coders.⁸ Eighty percent of the relationships and household types in 1850 received a code indicating the highest

inter-coder agreement. Inferences on the 1870 data therefore were checked through sampling. During the first coding operation (done by the author), each household type and each relationship within that household was given a confidence code of 1, if the coder was virtually certain of the inference made in terms of the coding rules; of 2, if there was considerable confidence in the inference made but some uncertainty (usually due to some minor deviation from the coding rules or when randomization had been used; see footnote 7); and 3, if there was considerable uncertainty about the inference made.

All of the 1870 households which received confidence codes of 2 and 3 and a five percent sample of those which received confidence codes of 1 were double coded and the two codings then were compared. In virtually every case in which the original coder had assigned a confidence code of 1, the second coder agreed. For households and relationships which had received a confidence code other than 1, the final code reflects an inter-coder consensus. All households receiving a confidence code of 3 were excluded from the analysis, and the confidence code itself is one of the independent variables included within it.

The following information is available in the 1870 census schedules: the number of each dwelling house and family in order of visitation, the name of each person whose place of abode was within that family, their age, sex, color and occupation,⁹ the dollar value of the real estate and personal estate owned by each person listed (as given by the respondent), their place of birth as well as whether their mother and father were foreign born, the month of their birth or marriage (if born or married within the census year), whether or not they could read or write, whether they were deaf and dumb, blind, insane or idiotic, whether they were male citizens of the U.S. of 21 years of age or older and whether or not, among this group, their

⁶ Coding all persons with different surnames as unrelated could underestimate actual family relationships by excluding persons involved in common-law unions and children from previous marriages whose surname was that of their natural father rather than their stepfather. In order to overcome this difficulty, the following procedure was used: where there was good reason to believe that one or the other of the two possibilities mentioned had occurred (which was usually suggested by the order in which persons were listed on the schedules), they were randomly assigned to the kin or non-kin category.

⁷ This N represents the deletion of 22 households headed by Orientals whose names were incorrectly listed so that it was impossible to infer relationships from them, 35 households headed by blacks and Indians, and 18 households whose structure was indeterminable. Most of the Indian population resident within the city in 1870 was listed on separate schedule sheets and insufficient information made it impossible to distinguish households from each other or to infer relationships. Therefore, it was necessary to exclude them from the analysis.

⁸ I wish to acknowledge with thanks the work of John E. Lawson, Jr. and James E. Smith, who acted as second coders for the 1850 and 1870 data, respectively. Smith also made a major contribution to the analysis presented in this paper.

⁹ Only the occupations of males 15 years of age and older were collected in 1850. In 1870, most women reported their occupation as "keeping house." In the analysis of occupations, both responses—none in 1850 and "keeping house" in 1870—were treated as NAs.

right to vote had been denied or abridged on any grounds other than rebellion or crime.

The first ten items were also available on the 1850 schedules, with the exception of personal estate information. This paper will, in the first instance, present the results of analyzing comparable material for 1850 and 1870, aggregating the second data set into the same categories used to analyze the earlier one. The second set of findings for 1870, which includes some of the additional information available on the schedules for that year, is based upon categories more appropriate to the distributions within the sample.¹⁰

The analysis which follows looks at four dependent variables which represent households with varying types of structure.¹¹ They are non-family households, simple family households, simple family households which also included additional non-kin (to be referred to as "simple family plus others" households) and extended family households. The non-family households, as defined here, were those without marital or parent-child ties. They include persons living alone as well as households whose members were coded as being unrelated to the household head.¹² Simple family households were composed either of husband and wife, husband, wife and child(ren), or single parent and child(ren) families. The "simple family plus others" households were made up of a simple family, as defined above, plus other persons coded as unrelated to the head which might include servants, boarders, employees or any persons with different surnames. Extended family households were composed of a

simple family plus any additional relatives; they might also include unrelated "others." It should be remembered that since kin relationships were determined primarily through surname identification, the non-family and "simple family plus others" households may include some units that were extended along the female line.

The analysis relies primarily on the results of dummy variable regression techniques which have been converted into the class and adjusted means generated by Multiple Classification Analysis (see Andrews et al., 1975). Both the dependent and independent variables were treated in their dummy variable form and a separate equation for each type of household was calculated. Tables 1, 2 and 3 include all four dependent variables: each household type differentiated from all others.¹³ Statistically, the means presented in these tables were derived by computing the deviation of the category mean from the grand mean for each dependent variable and then adding that deviation to the relevant grand mean. The deviations of the category means from the grand mean are equivalent to unstandardized dummy variable regression coefficients. Possible interaction effects between independent variables have not been explored.

Tables 1, 2 and 3 report the class and adjusted means for each independent variable in relation to each type of household organization. Class means indicate the zero-order relationships between the independent and dependent variables, while the adjusted means represent the relationships that exist when all other variables in

¹⁰ B. Laslett (1975) analyzes the data for Los Angeles City and County combined. The 1850 data analyzed here is for the city alone. The only boundary changes affecting the city between 1850 and 1870 was an extension of 1.2 miles at its southern end in 1859 (see L.A. City Engineering Dept., 1928).

¹¹ See P. Laslett (1972) and Hammel and Laslett (1974) for a discussion of these household categories. Some deviations from the P. Laslett-Hammel typology have been used for analyzing the Los Angeles data (see B. Laslett, 1975).

¹² This category also includes households in which siblings were living without parents or spouse, since such units would contain neither conjugal nor parent-child ties; N=3 in 1850 and N=31 in 1870.

¹³ Knoke (1975) discusses some of the problems of using regression techniques on dummy dependent variables when the distribution is highly skewed. Under these conditions, an independent variable can have a negative effect on a dependent variable, which would be statistically meaningless. Knoke believes that regression techniques should only be used when each category of the dummy variable includes at least 25% of the cases. The data used in this analysis do not always meet this criterion. In 1850, only 16% of the households had an extended family structure and in 1870, 16% and 7% of the households were "simple family plus others" and extended, respectively. Although two negative results are generated in the analysis, they are extremely small. Furthermore, they are adjusted means, not actual ones, which reduces the problem of their interpretation.

the equation were controlled. When the dependent variable is dichotomous, as is the case here, the means can be read as the proportion or percent of households in that category of the independent variable that were (in the case of the class means) or would have been (in the case of the adjusted means) living in the specified type of household, and comparisons can be made across household types. Tables 1 through 3 also report significance levels, which indicate when a given class or adjusted mean is significantly different from the grand mean for that dependent variable.¹⁴ The results discussed in the text refer, except where indicated otherwise, to statistically significant adjusted means.

Extended family households were significantly more likely to have received lower reliability and confidence codes than any other household type. For this reason, it is important to use caution in accepting the results of this part of the analysis. Such a concern, however, need not affect consideration of the other household types. The individual characteristics analyzed are those of the household head—not of all individuals resident within a household. Distributions of these characteristics, therefore, refer to household heads only.

Family Structure in Los Angeles, 1850 and 1870

Comparing the distributions of household types in 1850 and 1870 (see the grand means in Tables 1 and 2) indicates some interesting changes over time. In general, there was an increase in the proportion of households with simpler structures and a decrease in the proportion of those with more complex structures. Non-family households increased from 23 percent to 31 percent, and simple family households increased from 29 percent to 46 percent. Simple family households which included

non-kin declined from 32 percent to 16 percent, and extended family households declined from 16 percent to seven percent. The nuclear or simple family was clearly the central form of family organization in both periods.

Economic Factors

The distribution of occupations¹⁵ in 1850 presented in Table 1 shows that 55 percent of the households were headed by persons in occupations not specifically agricultural (such as coopers, grocers, carpenters, blacksmiths, lawyers, physicians, merchants, etc.) while 18 percent and 19 percent were laborers and ranchers or farmers, respectively. Despite the economic growth and increased occupational differentiation within the city in 1870 compared to 1850, a smaller proportion of household heads were in non-agricultural occupations in the later period. The proportion of farmers increased slightly (from 19 percent to 21 percent) while the proportion of laborers almost doubled (from 18 percent to 30 percent). If the interpretation associated with occupation is correct, the potential for accumulation of wealth was reduced in the twenty years under consideration—was concentrated in the hands of a smaller proportion of the population (of household heads); changes consistent with the development of "capital" as Marx described it.

In terms of actual wealth as measured by real estate ownership, Table 1 shows that more than half of the population of household heads in 1850 owned some land, although the proportion owning land of the highest value (\$3,000 and over) was only 16 percent. A higher proportion of

¹⁴ These were computed from Andrews et al. (1975:51). Thanks are given to Susan Shuckett for her work on this part of the project. It should be noted that the significance tests computed on the difference between a category mean and the relevant grand mean are not independent between equations, since the four dependent variables are, in fact, different categories of a single nominal variable.

¹⁵ A set of almost 100 categories were used to code the occupational titles listed on the census schedules. They reflect differences in skill, status, income and education and are comparable to SES scales for modern occupations. In the 1850 and comparable 1870 analysis, persons reporting themselves as agriculturalists, farmers or ranchers were grouped together; persons reporting themselves as laborers were differentiated from other occupational titles and all other occupations listed were grouped together into a non-agricultural category. This last group was differentiated into professional and white-collar and craftsmen and semi-skilled workers for the reanalysis of the 1870 data.

^a $p < .05$; ^b $p < .02$; ^c $p < .01$; ^d $p < .002$. Significance levels refer to differences between that category of the independent variable and the grand mean.

* The small N in this category suggests the need for caution. The data, however, refer to the population (not a sample) of household heads.

household heads was landless in 1870 than in 1850, despite the fact that land subdivision was already well underway. (see Tables 1 and 2). This may indicate the decreasing importance of land in a more urbanized environment, but since Los Angeles' economy was still primarily agricultural, it also implies that fewer households owned the means of production of their own subsistence, which had been such an important feature of California's earlier history.

In 1850, household heads with no land were most likely to live in non-family households (and those who owned any amount of land were significantly less likely to do so). Few landowners with estates of the highest value headed simple family households, and a significantly higher proportion than any other land-owning group headed simple family units which included additional non-kin. The latter relationship was found also in 1870. Although household heads owning the largest amount of land in 1870 were least likely to head non-family households, the proportions (rather than the significance levels alone) indicate that more land owners headed non-family households in 1870 than in 1850.

The relationship between land ownership and heading an extended family household changed in the twenty years under consideration: in 1850, whether or not the household head owned land was not significantly related to heading this type of residential unit. In 1870, household heads who owned land of the highest value were significantly more likely to head extended families. In the earlier period, landless as well as land-owning household heads had access to the means of subsistence for extended family living; this was no longer the case twenty years later.

In terms of variation in potential for the accumulation of wealth as measured by occupation, laborers in 1850 (see Table 1) were least likely to head non-family households and more likely to head simple family households than any other occupational group; non-family households were most often headed by persons with non-agricultural occupations. Having a specific occupational skill can be viewed

* See note on Table 1 for levels of significance.

as a resource which might enable migration to a more favorable labor market if the local one was not satisfactory. If involvement in kinship ties was thought of as an impediment to mobility, family formation may have been postponed. Laborers, however, had fewer occupational skills. Migration, for these workers, was less likely to have the same potential for improving their economic position compared to non-migration. Thus, they may have been less willing to limit their family formation.¹⁶

In 1850, farmers were not significantly more likely than the average to head one type of household rather than another. This finding suggests that the functionalist explanation for the presence of a high proportion of extended family structures in past agricultural societies requires some specification. An extended family, the argument goes (see Parsons, 1959; Linton, 1959), provided a necessary agricultural labor force in the past; decline in the demand for this resource under more urbanized conditions reduced its functional necessity and, therefore, its frequency. The findings presented in Table 1, however, remind us that (1) agricultural activities vary in the degree to which they are labor-intensive; (2) that if land was plentiful and/or other economic alternatives were available, extended family living may not have been as necessary; (3) that several mechanisms are available for satisfying a demand for labor. High fertility¹⁷ and the utilization of an indigenous or migratory population of non-kin can substitute for the labor which extended family members could provide.

Los Angeles was particularly well-favored in terms of the availability of an almost cost-free Indian population which, after the secularization of the missions established by the original Spanish coloniz-

ers of the area, left a population with few skills either for self-maintenance or the ability to return to tribal life (see Fogelson, 1967; McWilliams, 1946). Indians formed an important part of the labor force on the Mexican ranchos prior to the American take-over and continued to do so through the early years of the American administration. Cleland (1969:58) describes the situation as follows:

As early as 1850 the *ayuntamiento*, or town council, confronted by the problem of feeding the multitude of Indian prisoners arrested every week—none of whom had enough money to pay even a nominal fine—hit upon the happy expedient of farming out the services of such prisoners to the highest bidders. Landowners, especially those who had large vineyards, quickly took advantage of the opportunity, and soon the use of enforced Indian labor on the ranchos became a matter of common practice. . . .

Under these circumstances, kin were not as necessary for pursuing agricultural activities as they might have been and, as Table 1 indicates, farmers were not significantly more likely than the average to head extended family households.¹⁸

The interpretation of these empirical results suggests that between 1850 and 1870, the importance of actual wealth increased and the importance of potential wealth declined. In the later period compared to the earlier one, persons with non-agricultural occupations (in contrast to the other occupational groups) were no more likely to head one type of household than another. Whether this reflects increasing opportunities within the growing city of Los Angeles so that migration—and postponing family formation—was no longer as important or as necessary for accumulation, or whether this finding reflects a decline in the degree to which potential would result in actual wealth cannot be answered by the data used in this analysis.

Some support for the second explanation is provided by the following quotation from a local newspaper in 1869 (Cleland, 1969:59):

¹⁸ It should be noted, however, that farmers were more likely to head extended family households than any other occupational group.

¹⁶ One way to test this interpretation would be to see if marriage age was lower for laborers than for persons with more specific occupational skills (net of other factors). Census data do not permit an analysis of this question. Research on the structure of marriage in nineteenth-century Los Angeles is now in progress.

¹⁷ This analysis will not discuss fertility. Attention to this subject is planned for the future.

"The Los Angeles *Semi-Weekly News* condemned the system of using enforced Indian labor, not on humanitarian grounds, but because degraded and inefficient Indians were 'being brought into competition with that class of labor that would prove most beneficial to the country,' checks immigration, and retards the prosperity of the country.'"

Nineteenth-century Los Angeles was successful in attracting "more efficient" labor through high rates of "Anglo" immigration. If a large proportion of these new in-migrants replaced the Indian laborers used earlier, they were less likely to have the same potential for further mobility that might have been available to them in the earlier period.

Table 3 presents a reanalysis of the 1870 data which includes personal as well as real estate among the independent variables.¹⁹ The results provide additional support for interpreting changes in household structure in terms of the economic preconditions necessary for the development of capitalism included in Marx's discussion of "the so-called primitive accumulation." Personal estate is more moveable wealth than real estate and, as such, can be viewed as a potential source of capital rather than simply as a means of subsistence. The transformation of the means of production into capital is, as we have seen, a central feature of Marx's analysis of the development of capitalism. Its impact on household organization is, then, of particular importance for the interpretations presented in this paper.

¹⁹ Table 3 includes four new independent variables: a valuation in dollars of the household head's personal estate, literacy, and whether the head's mother and father were foreign-born or native-born. (Literacy information was available on the 1850 schedules but was not included in the original analysis.) Some of the data analyzed earlier has been aggregated into different categories which reflect changes in the distribution of these characteristics over the two decades.

The effects of personal estate on household structure are discussed in the text. None of the other additional variables add much to understanding household organization in 1870 Los Angeles except the effect of father's birthplace. A native-born (compared to foreign-born) father seems to have been an "inheritance" which provided a greater opportunity for family formation. Mother's birthplace, however, was not important in this respect. Literacy did not have an effect.

Table 3 shows that the value of the real estate owned by the household head had a significant effect only in relation to the non-family and "simple family plus others" households and did not affect the extended family unit. This difference can be accounted for by the availability of the value of the household head's personal estate in the analysis presented in Table 3.²⁰ The impact of actual wealth on heading an extended family household reflects the relationship between the highest valuation of personal estate, not land, the effect of which disappeared when personal wealth was entered into the equation. Since these two indices of wealth are highly correlated ($r=.301$; $p<.001$), the distinction between them was obscured in the analysis presented in Table 2. Wealth appears to have been necessary in order to maintain complex households, as Goode (1963) has suggested. In nineteenth-century Los Angeles, however, extended family households do not seem to have been the result of landowning and/or the agricultural services which extended kin might perform; it was due, rather, to the availability of personal estate which could be used to hire wage laborers as well as to support the additional burden of dependency which extended kin might represent.

Table 3 also allows us to see changes in the relationship between occupation and household structure when personal estate is included in the analysis and the non-agricultural category is differentiated into white-collar and upper blue-collar occupations. This analysis of the 1870 data shows both farmers and laborers to be less likely than the average to head non-family households while laborers, as well as more skilled manual workers, were more likely to head simple families. While the analysis in Table 2 shows that household heads in non-agricultural occupations were not more likely to head one type of household organization than another, this was in fact due to the effect of the white-collar group within this category; house-

²⁰ Enumerators were instructed to list the value of the personal estate only if it was \$100 or more (see Wright, 1900). The categories presented in Table 3 reflect that instruction.

hold heads in upper blue-collar occupations were not only more likely to head simple family households but they were less likely to head simple families that included additional non-kin. It was the household heads in white-collar occupations only who were no more likely to head one kind of household rather than another. If occupational groups differ in their potential for accumulation and this variation affects household organization (as the conceptual model suggests), its impact was felt among manual but not white-collar workers—at least in the stage of development that Los Angeles had reached by 1870.

In the second analysis of the 1870 data, farmers remained more likely than the average to head households which included "others"; non-kin appear to have been the primary labor supplement to nuclear family members among farm households, regardless of their personal wealth. Craftsmen and semi-skilled workers were less likely to head households which included additional non-kin, while laborers were not significantly different from the average in this respect. These findings suggest that the wage levels of laborers may have been sufficiently low to lead some of them to supplement their incomes by taking in boarders while this appears to have been less true for other, perhaps more highly skilled and better paid manual workers. (Income data, not available on the census schedules, is obviously necessary to test this interpretation directly.) Thus, while the potential for accumulation through mobility may have become more equal between manual workers, this was not necessarily true for their actual wealth from wages.²¹

Looking at the effects of personal estate itself, Table 3 shows that household heads with no personal wealth were more likely than the average to head non-family

households, while most groups who owned any personal estate at all were less likely to do so. This finding suggests that the increased proportion of non-family households in 1850 compared to 1870 was due, at least in part, to a larger proportion of poor people in the population, i.e., those without any personal wealth. This was also true, as Table 1 indicates, of household heads who owned no real estate in 1850 but not in 1870. That wealth measured by personal estate should have become a more important determinant of household structure than wealth from real estate in 1870 compared to 1850 is not surprising given the more urbanized nature of the community in the later period. The changing distribution of household types over time, however, seems to have been due to the decreasing availability of wealth of any kind.

Household heads with the smallest amount of personal estate were more likely to head simple family households, while the opposite was true for the wealthier group. Owning the greatest amount of personal wealth was positively related to heading an extended family household and negatively related to heading a simple family household that included non-kin but not extended kin. Despite the economic capacity for resident servants in the wealthier households, only four percent of all the households included in this analysis had servants specifically mentioned as resident members.

The economic variables included in this analysis have provided the basis for interpreting changes in household structure in nineteenth-century Los Angeles that are consistent with macro-economic developments which Marx associated with the growth of capitalism. Changes in an individual's actual and/or potential for the accumulation of wealth, it was suggested earlier, is one way to link structural changes associated with "the so-called primitive accumulation" and household organization. While questions might be raised about the measurement of individual accumulation in the data analyzed here, the findings provide significant and consistent support for the interpretations suggested by the formulation developed in this paper.

²¹ An increasing differentiation in actual wealth among manual workers is likely to be of considerable importance for understanding working-class behavior, especially as it may relate to the development of a split labor market (see Bonacich, 1972). Tygiel (forthcoming) discusses some of the effects of working-class differentiation on household composition, residence patterns and politics in nineteenth-century San Francisco.

The Family Life Cycle

Recent historical research (see, for example, P. Laslett, 1972; B. Laslett, 1975; Demos, 1968; 1970; Greven, 1966; 1970; Parish and Schwartz, 1972) has demonstrated the predominance of nuclear family households in preindustrial agricultural societies. One explanation for these findings is demographic (Burch, 1972; Levy, 1965; Berkner, 1972). Societies with late marriage ages and high mortality, characteristic of western Europe in earlier times (Hajnal, 1965), were limited in the degree to which extended families could occur, except for brief periods at the beginning and/or end of the family life cycle. Variation in demographic factors is, therefore, important for understanding changes in household structure over time. In relation to the economic interpretation presented in the preceding section, it is necessary to see whether and how demographic factors are related to them.

Limitations of the data used here make it impossible to address directly several of the issues mentioned above. Neither mortality information nor age-at-marriage are available on the census schedules.²² Previous historical research on the family, however, has used the age of the household head as a way to investigate the family life cycle (see, for instance, Berkner, 1972; Herlihy, 1972; B. Laslett, 1975). This procedure has been followed in the analysis presented here. The relationships between the age of the household head and family structure in both 1850 and 1870 indicate the effects of social change on the family life cycle.

The youngest household heads were more likely to head non-family house-

holds in both 1850 and 1870. In 1850, however, heading a simple family was a feature of late middle age, persons 50-59 years old were the only group significantly more likely than the average to do so. The proportion of simple family households headed by all persons 30 years of age or older, however, increased between 1850 and 1870, and only households headed by those in the 40-49 age group were significantly more likely than the higher average to head them.

The previous section suggested that the potential for the accumulation of wealth declined between 1850 and 1870. Actual wealth is also likely to have narrowed; a smaller proportion of household heads were landowners and the percent of household heads in unskilled labor occupations increased. Since wealth was associated with more complex household types, the decreasing access to this economic resource could, in part, explain the changing distribution of household types over the twenty-year period. The changing relationships between age and household type provide a further explanation for these different distributions. Heading a simple family household was no longer one phase of a differentiated pattern of family life-cycle stages but was the dominant organizational form of family life throughout its entire span. In 1870 as in 1850, the oldest age group was significantly more likely to head an extended family unit but the proportions (in their adjusted form) had declined from 33 percent to 14.5 percent. Furthermore, the simple family was the modal category for the eldest as it was for all but the youngest household heads in 1870, which was not the case in 1850.

One further observation can be made when looking at the changing effects of age on household organization over this twenty-year period. The smaller proportion of simple families which included additional non-kin in 1870 compared to 1850 suggests that persons who had not formed family alliances of their own in 1850 were, nevertheless, likely to live within a family (compared to a non-family) context; by 1870, such persons were more likely to remain outside of a familial unit throughout their entire adult lives.

²² Data on marital status were not available on the U.S. federal census schedules until 1880. It is therefore impossible to know how many persons heading non-family households were divorced, separated or widowed. Since non-family households did not include a marital link to the head, some inference can be made about the marriage ages of non-family household heads: 56.8% of all households headed by persons under 30 were non-family in 1850 and 51.9% were non-family in 1870. This indicates that residents of Los Angeles also may have followed the western European pattern of later marriage ages than has commonly been assumed.

If migration potential was considered to be a resource for the accumulation of wealth and kinship ties were seen as antagonistic to it, more persons may have postponed marriage in the hope of improving their economic positions. For those who were unsuccessful in turning potential into actual accumulation (and it was the least wealthy who were most likely to head non-family households), their attractiveness within the marriage market was likely to decline with age. Thus, what may have been a decision to postpone marriage in earlier years could have resulted in a limited ability to establish one's own family or to live within a family at all at a later age.²³

In general, then, there seem to have been two major shifts in the life cycle of nineteenth-century Los Angeles families between 1850 and 1870, one of which relates to the placement of kin and the other to the placement of non-kin. In 1870 compared to 1850, non-kin were less likely to live in households which included conjugal and/or parent-child relationships within them and kin were more likely to live within their own simple families rather than being connected to another, related kin group. Thus the proportion of both simple and non-family households increased and the proportion of "simple plus others" and extended family households declined. One consequence of this change is that as the structure of the family life cycle became simplified, the ability of families to respond to changing life-cycle needs through structural adaptations, such as taking in boarders, was reduced. Wages, therefore, became more important for family subsistence.

Sex Roles and Household Structure

Household units have been, and still are traditionally headed by men. Although this is not a universal phenomenon either in time or across cultures (see Boulding, 1976), women in western societies have tended to head households less by choice than by circumstances, such as widowhood, divorce or separation. In Los Angeles, 18 percent and 14 percent of the

households analyzed in 1850 and 1870, respectively, were headed by women. Although the proportion of female-headed households was not markedly different in the two time periods, the relationships between sex and household structure changed. The following discussion provides an opportunity to see whether or not the macro-economic developments already described can account for these changes as well as providing a basis for exploring sex roles in a developing nineteenth-century community.

The role of women in nineteenth-century California can also be viewed in terms of the actual and/or potential access to the accumulation of wealth which has been applied in earlier sections of this analysis. Both actual and potential wealth historically has been available to California women through their ability to inherit property. Women in non-industrial societies also have an additional potential for the accumulation of wealth through trading or agriculture varying, however, by the type of agricultural technology. (Boserup, 1970).

The earlier analysis of household structure in mid-nineteenth-century Los Angeles (B. Laslett, 1975) shows that women were more likely to head extended families than any other type, while this was not true for men. Since this empirical result controlled for the effects of actual land ownership, it suggests that a generalized authority may have been available to women in a society in which their inheritance rights were legally protected and they had access to economically productive roles.

To have access to both wealth and authority at one point in time, however, does not necessarily ensure its continuation. Recent discussions of women in contemporary third world countries suggest that their position has declined with modernization (see, for instance, Tinker, 1976). Whether or not this was also true in the development of western nations only recently has begun to be explored (see, Shorter, 1975; Scott and Tilly, 1975; Hartmann, 1976). The data available in this analysis provides the opportunity to address this question in one nineteenth-century American city.

²³ Tygiel (forthcoming) reports a similar pattern in late nineteenth-century San Francisco.

Table 4. Relationship of Sex of Household Head to Type of Simple Family: Los Angeles, California, 1870

Household Type	Household Head		N
	Male %	Female %	
Married Couple Alone	100	0	77
Married Couple with Child(ren)	98.2	1.8	275
Single Parent and Child(ren)	31.6	68.4	76

$p < .0001$.

Table 1 shows that, in 1850, women were less likely than average to head non-family households and, as already mentioned, were more likely to head extended family households, independent of the other variables included in the analysis. By 1870 (see Table 2), women were still less likely to head non-family households, but they were also less likely to head extended family households. Table 2 also shows that, in the adjusted form of the relationship, 76 percent of women heads of households were in simple families compared to 41 percent of men.

This result masks another finding, since the simple family category includes households composed of husband-wife alone, nuclear families with children and single parent-child(ren) families. Women were most likely to be designated as the household head when a spouse was not present (see Table 4). They were, then, heading single parent-child families more than any other type. While a similar distribution is found among simple family households in 1850, this was not the modal household category headed by women.

These empirical results refer to the adjusted form of the relationship between sex and household structure and are independent of the effects of land ownership. The changing relationship between sex and household structure was not, therefore, caused by differences in the actual wealth of female heads of households as measured by real estate ownership. For 1870, however, another measure of actual wealth is available—personal estate—and, as suggested earlier, personal estate may have been of greater economic im-

portance in the later period. The inclusion of personal estate in the analysis, however (see Table 3), does not affect the relationships between sex and household structure already discussed. Since differences in women's access to actual wealth does not seem to account for the 1870 relationships, changes in their potential for the accumulation of wealth may offer a tentative explanation.

Wage-paying work for women was severely limited in this period of Los Angeles' history. Factory jobs, a source of female employment in the more industrialized areas of New England, were not available and Indian women who served as domestics in the pre-American period (Fogelson, 1967:9) may have been a cheap source of household service workers in the later period as well. Women's access to the new skills associated with industrializing economies historically has been more limited than men's (Hartmann, 1976) and appears to be a continuing pattern in currently developing societies (Tinker, 1976; Youssef, 1974). It seems reasonable, therefore, to infer that women's potential access to the accumulation of wealth declined between 1850 and 1870, and that this affected the observed relationships between sex and household structure.

The problem of women's restricted access to economic roles is not characteristic of capitalist societies only (see Scott, 1974). Thus, while the changing position of women in nineteenth-century Los Angeles may have been affected by the macro-economic changes which Marx associated with the early stages of capitalist development, they do not appear to be limited to them.

Migration and Ethnicity

High rates of geographic mobility have often been used to explain changes in the distribution of family types over time since kinship ties, it has been suggested, are more attenuated in modern societies than in the past (which is assumed to have been more geographically stable). In this analysis it is, in fact, impossible to disaggregate the net effects of ethnicity and

migration²⁴ from each other, since most Anglos were also migrants (and thus, for this group, there is virtually no variation on migration) while most Spanish-surname persons were born in California or Mexico (and thus there is almost no variation on ethnicity).²⁵ While this statistical problem inhibits interpretation of the net effects of ethnicity and birthplace on household structure independent of each other, it also suggests some possible sources of specification which may contribute to understanding the effects of these variables in nineteenth-century Los Angeles and, perhaps, elsewhere as well.

All types of migration are not equally disruptive of family ties. Overall migration includes at least two potentially different types: (1) first-generation migration into a new area of settlement and (2) later migration from the same place of origin. Later migrants from areas of earlier migration are likely to have an easier time becoming part of the existing social networks in the new place of residence than earlier ones. If this distinction between earlier versus later migration can help to explain household structure, its effect should weaken over time as migrant groups establish more extensive linkages within the community.

Ethnicity often has been used to measure cultural differences between groups; it can, however, also be viewed in other ways. As such, the effects of ethnicity may depend on structural attributes of the ethnic group within a given social context

such as its size, socioeconomic position and degree of segregation.²⁶

The class means in Table 1 show that, in 1850, persons born in Mexico and California were less likely to head non-family households, despite the fact that one was a migrant and the other a non-migrant group, while migrant heads born elsewhere were more likely to do so. Mexican-born (migrant) heads were also more likely to live in simple families, while this is not true for other migrant heads. The migration status of the household head seems to be related only to simpler, not more complex, forms of family organization but in varying ways. The zero-order effects of ethnicity show that Anglos were more likely and Spanish-surname persons less likely to head non-family households, with the reverse set of relationships being true for simple family households.

While the class means report the actual zero-order relationships, only adjusted means can measure the net effects of these independent variables. Yet it is precisely this which cannot be done from these data. In discussing the adjusted means, therefore, the interpretations are suggestive only, since the data cannot address them directly.

In the adjusted form of the relationships between birthplace and household type, Table 1 shows that households headed by persons born in Mexico were more likely than average to head simple family households while other migrant heads were significantly less likely to do so, which repeats the relationships observed in the class means. Migrant heads born elsewhere, on the other hand, were significantly more likely to head simple family households which included non-kin.²⁷

²⁴ Birthplace is being used as a proxy variable for migration, with all California-born household heads considered as non-migrants and all household heads born elsewhere considered as migrants. Using birthplace data for this purpose may underestimate actual migration into Los Angeles by persons born elsewhere in California.

²⁵ The first party of Anglo pioneer settlers arrived in California in 1841 (Caughey, 1970: 136), while migration from Mexico dated back to the eighteenth century. In both 1850 and 1870, a small number of Spanish-surname household heads were, however, born in South America and Spain, and an even smaller number of Anglos were born in California. Thus, no birthplace-ethnicity cells were empty. While the net effects of ethnicity and migration cannot be disaggregated, the adjusted means can be discussed as independent of the effects of the other independent variables included in the computations.

²⁶ Although ethnic and/or migration groups may vary in socioeconomic status, the adjusted means for ethnicity discussed in the text are net of the economic variables included in the analysis. This factor therefore cannot be used to explain the results.

²⁷ The only significant adjusted relationship between ethnicity and household type shows Anglos to have been less likely to head "simple family plus others" households, which contradicts the last result mentioned and is a statistical artifact of the non-independence of the migration and ethnicity variables. These contradictions are also a consequence of the distribution of cases on the independent varia-

These findings suggest that the two different specifications reviewed earlier in this section are relevant to understanding the effects of ethnicity and migration on household structure. Second or subsequent-generation migrants taking historically traditional routes may (1) be more likely to travel within simple family groups and/or (2) may find it easier to establish linkages with the local population which will facilitate their chances within the available marriage market. (Earlier marriage, however, may have a negative impact on the accumulation of wealth.) However, first-generation migrants, especially if they differ culturally from the resident population, may tend to be segregated along ethnic lines.²⁸ Thus the ethnic structure of the receiving area and the migration history of incoming groups may be relevant to understanding the effects of these variables on household organization.

In 1870, Los Angeles had a larger proportion of immigrant household heads than in 1850: 60 percent were born outside California in the earlier period and 83 percent in the later one. As in 1850, both the class and adjusted means show that Mexican-born migrant heads were less likely to head non-family households. No other adjusted relationship between birth-place and household structure reaches a statistically significant level; effects of migration seem to have disappeared. If migration has an impact on household structure, it may operate only in the earliest years of settlement by a new immigrating group.

The proportion of households headed by members of the two major ethnic groups in the area was almost completely reversed in the two decades between 1850 and 1870. More than two-thirds were Spanish-surname in the earlier period, while almost the same proportion were Anglo by the later one. In 1850, the ethnic-

ity of the household head was almost wholly unrelated (via statistically significant adjusted means) to household type. In 1870, however, more significant relationships can be observed. Spanish-surname household heads were less likely than average to head non-family households and more likely to head simple families. The opposite pattern can be seen for Anglo household heads.²⁹

Whether or not change in the proportion of the two major ethnic groups within Los Angeles between 1850 and 1870 and the increasing political and economic dominance of Anglos over the Spanish-surname population during this period (Pitt, 1970) served to heighten cultural differences between them, at this point, can only be a matter for speculation. It should be noted, however, that ethnicity, to the extent that it does affect family structure, continues to be associated only with the simpler, not the more complex types of households.

Summary and Conclusions

The materials presented in this paper are both complex and varied. Among other things, they point to the richness of census data for studying changes in family structure over time. With this one source of easily obtainable documentary data, it has been possible to consider a range of theoretical and empirical questions relevant to family structure and social change. In this respect, scholars owe thanks to the Cambridge Group for the History of Population and Social Structure for their pioneering work in developing quantitative family history.

The overall pattern of findings reported in this paper suggest that changes in the macro-economic structure which Marx associated with the development of capitalism can contribute to understanding family structure in nineteenth-century Los Angeles. The changing relationships of individual attributes to household organization, particularly as they reflect ac-

bles, a factor which affects other results presented in the tables as well.

²⁸ The 1850 Los Angeles data show that boarding was indeed segregated along ethnic lines: 91% of Spanish-surname boarders lived in households headed by Spanish-surname persons and 96% of Anglo boarders lived in Anglo-headed households. The 1870 percentages are similar.

²⁹ The 1870 analysis is affected by the relationship between ethnicity and migration as it was in 1850. The discussion of these results, therefore, only can be suggestive.

tual and/or potential access to the accumulation of wealth, can be interpreted consistently in terms of the transformation of the means of production into capital and the increasing dependence of workers on wage labor for their means of subsistence. These factors are likely to have affected the adaptability of the residential family to the demands which life-cycle variation and economic fluctuations made upon it and have major implications for understanding both the nineteenth- and twentieth-century American family. Further elaboration of the theory developed here must take account of these changes in the macro-economic structure in order to understand both the outcomes of social change in relation to the family and the processes by which these changes came about.

The nature and effects of social class in relation to the family during the development of capitalism has not been specified in this discussion. It seems likely that class relationships would reflect conflict over the efforts of groups which differed on the actual/potential dimensions to maximize or maintain their wealth and/or status positions. Easterlin's (1976) explanation for reductions in nineteenth-century American farm fertility, which emphasizes the decline in opportunities for capital accumulation, is consistent with the positions developed in this paper. Further empirical research is required to more fully understand changes in the family as capitalism developed.

No attempt has been made in this presentation to statistically analyze the temporal sequencing of the relationships discussed. It appears likely, however, that as changes took place in the social organization of economic activities, their impact was felt in the distribution of household types and in changes in the family life cycle and sex roles, particularly in relation to women, as well as other features of family life which this analysis has not been able to address. As the macro-economic institutions were changing from means of subsistence into capital, actual wealth became a relatively more important determinant of household structure and the impact of potential wealth seems to have declined.

An adequate causal model which would attempt to specify these processes, however, must not look at the effects of economic variables alone. As the analysis here suggests, other factors such as sex, life cycle and networks of social integration (which may reflect migration history and ethnicity) may be important intervening variables. The explanation would be tested, however, by asking—at each stage of analyzing the temporal process—whether or not changes in the actual or potential accumulation of wealth affected by these intervening variables can satisfactorily explain the observed results and, furthermore, whether or not changes in wealth accumulation are significantly affected by the economic and political structure of capitalist property and class relationships.

This paper discusses the general theoretical issues about social change and the family which have concerned sociologists and historians for many years. Criticisms of Engels' (1972) analysis of the family over time has led, perhaps, to a premature rejection of a Marxian approach for analyzing this problem. If the interpretations of changes observed in nineteenth-century Los Angeles are correct and can be replicated through studies of other areas and time periods, further attention to a Marxian perspective would be appropriate. The analysis presented here suggests that the variables and dynamics implied by this perspective have considerable explanatory potential for understanding both social change and the family.

DETERRENCE AS SOCIAL CONTROL: THE LEGAL AND EXTRALEGAL PRODUCTION OF CONFORMITY*

ROBERT F. MEIER

University of California, Irvine

WELDON T. JOHNSON

University of Wisconsin, Madison

American Sociological Review 1977, Vol. 42 (April):292-304

Previous work dealing with the deterrent effects of legal sanctions has lacked an appropriate sociological context. This paper adopts a theoretical perspective which views legal threats as only one mechanism which may produce conformity. Our framework, which is consistent with both the social control and social influence literature, emphasizes the possible importance of extralegal factors in the production of conformity. We illustrate the methodological implications of our approach empirically with a test of the deterrence doctrine that focuses on the use of marijuana. A multiple regression analysis of data obtained from a sample of both marijuana users and nonusers in a jurisdiction with severe penalties for the use of marijuana indicates that the criminal law receives support from certain extralegal inhibitory influences. Moreover, when the relative efficacy of these extralegal influences are compared to the controlling effects of legal threats, the extralegal influences are found to be the more important.

Studies of the deterrent effects of law have recently enjoyed a renaissance of both scholarly and public interest. Because of its importance for public policy, deterrence research has been prominent in current legislation and litigation, as well as in forums devoted to crime.¹ However, despite the flurry of research in this area and the sanguinity with which many sociologists view the deterrence doctrine, writers agree that we are still some way from being able to specify fully the conditions under which legal sanctions produce a deterrent effect (Tittle and Logan, 1973;

Tullock, 1974). This unsatisfactory state of knowledge has been attributed both to methodological differences in research and measurement techniques and to the ideological predisposition of analysts (Erickson and Gibbs, 1973; Wilson, 1975: ch. 3).

One path toward addressing unresolved issues would be to strive for more adequate research; that is, to conduct studies which are not only methodologically sound, but also operationally comparable. A quite different strategy, however, recently has been proposed by Gibbs (1975) who recommends a moratorium on conventional studies of deterrence. In Gibbs' view, what is needed now is a restatement of the deterrence doctrine as a sophisticated sociological theory. This requires integrating deterrence research with what else is known about "preventive mechanisms"—including a consideration of punishment properties other than, and in addition to, the severity and certainty of the sanction—and especially the extralegal conditions that also may inhibit criminal behavior.

The contention of this paper is that important conceptual and methodological issues surrounding deterrence have yet to be addressed, and that the resolution of these issues requires departures from previous deterrence formulations. This paper proposes an alternative conceptualization

* An earlier version of this paper was presented at the annual meetings of the American Sociological Association, San Francisco, California, August, 1975. This research was partially supported by the National Institute of Mental Health (Grant 1-R01-DA00853-1) and the Research Committee of the University of Wisconsin Graduate School. We gratefully acknowledge the substantive suggestions and advice of Gilbert Geis, Robert E. Petersen and John DeLamater, as well as the anonymous reviewers of this journal.

¹ One study, for instance, of the deterrent effects of capital punishment has figured prominently in arguments before the Supreme Court on the constitutionality of the death penalty (Ehrlich, 1975). The results of this study—that, on the average, every execution in the United States during the period 1933–1967 deterred eight potential murders—has become the topic of discussion not only in professional and academic circles, but also in popular speculations about crime and punishment. A critique of this study can be found in Bowers and Pierce (1975).

of deterrence, one which anchors deterrence in a larger context of social control where legal threats constitute just one mechanism that may produce conformity.² The shift in perspective recommended here is consistent with the emergence of "control" theories of crime and delinquency. Whereas conformity previously was viewed as a given, control theories view it as problematic; the question "Why do they do it?" is replaced by a new question which inquires about the conditions of conformity, i.e., "Why don't they do it?" (Hirschi, 1969: 10-1). One answer, of course, is deterrence. Finally, after introducing this alternative approach, we present a preliminary empirical application to one widely violated criminal prohibition: the possession and use of marijuana.

DETERRENCE IN DOGMA AND THEORY

The deterrence doctrine, as formulated within criminology, is strikingly atheoretical both in its philosophical origins and its historic inattention to developments in the social sciences. As Gibbs (1975: 5) notes, deterrence is more a doctrine than theory, "a vague congerie of ideas with no unifying factor other than their being the legacies of two major figures in moral philosophy, Cesare Beccaria and Jeremy Bentham." In criminology, the philosophical origins of the deterrence doctrine apparently discouraged subsequent sociological scrutiny of the concept's ontological status. The hypothesized deterrent effect was not generated by systematic observations of the relationship between legal sanctions and behavior, but from a body of social thought which invoked the concept of deterrence as a justification for an alternative legal system. Consequently, although classical deterrence doctrine implicitly contains claims about human motivation (Taylor et al., 1973:

2-3), these claims were developed to justify reform, not to explain behavior. Ultimately, criminology granted deterrence the status of a scientific concept or, at least, as a researchable hypothesis, although subsequent conceptual development of this hypothesis again occurred outside the behavioral sciences. Johannes Andenaes, a legal scholar, is usually credited with stimulating modern interest in deterrence. More recent conceptual activity was similarly influenced by an essentially jurisprudential orientation (Hawkins, 1969; Zimring, 1971; Zimring and Hawkins, 1973; Andenaes, 1974; 1975).

In contrast, the role of social scientists generally has been restricted to nonexperimental tests of the formulations developed by students of jurisprudence. Such tests have dealt narrowly with the impact of legal sanctions on criminal behavior, where legal sanctions are the independent variables and crime rates the dependent variable (see Andenaes, 1974: passim). The empirical energy directed toward this relationship shows an uncritical acceptance of the deterrence doctrine without a corresponding theoretical rationale that is based on established principles of social influence and control. This restricted conception of the deterrence doctrine is evident both in the more formal definition of deterrence and the kinds of empirical problems to which this conception traditionally is directed.

Deterrence, Control and Compliance

In criminology, the concept of deterrence is used to describe the prevention of criminal behavior through the use of, or by the threat of, legal sanctions. The criminal law, through its content and application, designates those acts which are proscribed and identifies the legal penalties associated with them. "To the extent that these stimuli restrain citizens from socially undesired actions which they might otherwise have committed, a general preventive effect is secured" (Andenaes, 1974: 35). Deterrence, then, is intended to refer to compliance produced by the existence and administration of the criminal law rather than some other source. So defined, deterrence refers to a

² We use the term "social control" to apply to all social mechanisms invoked to establish, inhibit or change human behavior. To us, social control does not connote any fundamentally different concerns than the term "social influence," except that the former is more often used by sociologists and the latter by social psychologists.

particular *relationship* between the existence, or perception, of legal sanctions and subsequent behavior. Deterrence refers not to sanctions and behavior in isolation but, rather, to one of their possible relationships. The specific relationship of interest is one in which a particular sanction functions to prevent the occurrence of an act; the sanction is thought to decrease the probability of the act's occurrence.

Stated in this way, the deterrence doctrine may be integrated with two related bodies of literature—social control and social influence-compliance. The social control literature describes mechanisms which preserve social order and perpetuate social organization. The concept of social control is often used to account for conduct that is not wholly explained by socialization and situational interaction (e.g., LaPiere, 1954:v). Others use the concept to refer to both internal mechanisms, such as the internalization of norms, and external mechanisms that control behavior, including the manipulation of sanctions—rewards and punishments (Olsen, 1968:124–9). It is clear that the deterrence doctrine refers to this more general sanctioning-behavior relationship, but is more limited in its focus on legal sanctions to the exclusion of others. There is no theoretical reason, however, why the relationship between legal sanctions and behavior should be examined differently than other sanction-behavior relationships.

Most discussions of deterrence blur the potentially important distinction between the intended and actual consequences of control mechanisms. While the former refers to mechanisms which are intended to inhibit, regulate or control behavior, the latter pertains only to those mechanisms which actually do inhibit, regulate or control behavior. The labeling perspective of deviance, for instance, clearly adopts the intended conception of social control; if these mechanisms actually did control behavior, there would be no reason to speak of secondary deviance since, by definition, the deviance would have been controlled in its primary stages.

The actual consequences conception places deterrence in a broader context,

and directs attention to the role of deterrence in the more general context of social control. If deterrence is only a *possible* source of conformity, the question becomes whether or not the fear of legal sanctions is a mechanism of social control. Moreover, the anticipation of legal sanctions, obviously, is not the only possible influence on behavior, nor can it be understood without explicit reference to other social controls because "there is always a complicated interplay between the law and the multitude of other factors which shape our attitudes and behavior" (Andenaes, 1974:1). In short, the task for the student of deterrence is to explain the relationship between behavior, on the one hand, and both legal and extralegal sanctions on the other.

The parallel between deterrence and social influence theory is also manifest. In principle, the deterrence doctrine is basically no different from other sanction-behavior relationships in social influence situations, though an essential difference is that deterrence is concerned with a particular *source* (the legal sanction), a *signal* (a threat) and a *target* (violators or violations of the sanctions). The deterrence doctrine—like social influence theory—anticipates that compliance is determined by certain characteristics of the source such as severity, certainty and celerity, and characteristics of the target such as personality, behavioral commitment, and the instrumental and symbolic dimensions of the act (Chambliss, 1967; Tittle and Logan, 1973; Zimring and Hawkins, 1973).

Perhaps the most useful parallel to be drawn, however, is in the concept of *threat*. The criminological literature implies that the specific mechanism which deters is the threat of detection, apprehension and punishment for non-compliance. Thus, deterrence occurs when "... a threat causes individuals who would have committed the threatened behavior to refrain from doing so" (Zimring and Hawkins, 1973:71). Indeed, the deterrence literature differentiates threats that are communicated by the experience of others who suffer the consequences of violation ("general deterrence") from threats which are com-

municated through personal experience of these consequences at an earlier time ("specific deterrence"). In this sense, criminology's deterrence doctrine pertains to just one potential determinant of compliance: the unilateral, contingent threat.³ The legal threat becomes only one of several kinds of signals or messages that may influence behavior; and, in either area of inquiry, the relevant research question is not whether the signal or sanction actually deters, but under what conditions it does so.

Are Crime Rates Relevant?

These conceptual matters suggest two important empirical considerations for nonexperimental research designs. First, the concept of deterrence must be anchored within a broad context of human motivation. The legal threat may indeed generate conformity, but there is no reason to presume that the law operates in a social influence vacuum. In this regard, the task for deterrence research is somewhat larger and more difficult than anticipated. The deterrence hypothesis *requires* that the multiple sources of conformity be identified; only one of these is legal threat. Furthermore, the deterrence hypothesis requires the estimation of the relative efficacy of these different factors. For these reasons, the conventional bivariate conceptualization of deterrence as the relationship between legal sanctions and crime is insufficient.⁴

The second implication is that the study of deterrence must depart from the traditional unit of observation—the crime rate. Previous research seems not to have recognized that deterrent effects cannot

be indicated by crime rates. Indeed, crime rates may be logically irrelevant to the study of deterrence insofar as they can only indicate who has *not* been deterred. Research on deterrence must utilize observations of both compliance and non-compliance.

It is noteworthy that deterrence research has proceeded rather differently. Typically, deterrence research has examined the relationship between some measure of a sanction characteristic and some measure of criminal behavior, using a bivariate correlational analysis, or a variant of a chi-square test, to assess the strength of the association.⁵ With some variation, this has been the conventional approach to this problem both by sociologists (see, e.g., the summary contained in Gibbs, 1975: ch. 5), and by economists (see, e.g., the papers contained in Becker and Landes, 1974). Once the matter was so defined, the remaining issues have been seen principally as solutions to various methodological problems that relate either to the measurement of the criminal behavior, the inclusion of other indicators of the sanction characteristics, such as perceptual measures, the operationalization of the sanction characteristics, or the appropriate mode of analysis, such as the alternatives offered by the econometricians.

When the relationship between the characteristics of a sanction and the rate of crime is scrutinized for evidence of deterrence, substantial inferences must necessarily be made. It must be presumed, for example, that the reciprocal of the crime rate—the rate of nonviolation—constitutes the "deterrence rate." But, the rate of nonviolation may actually reflect *two* sources of compliance: (1) compliance produced by influences other than a legal threat and (2) compliance produced by legal threats—deterrence. This

³ An interesting analogue to deterrence research is found in the experimental analysis of punitive contingencies explored in studies of interpersonal risk (Marwell and Schmitt, 1975) and threats (Tedeschi, 1970; 1972). This experimental approach appears to be a major alternative methodology to that used in this study.

⁴ There is no basis for presuming that other (extra-legal) influences are somehow "controlled" when the bivariate relationship between legal sanctions and crime is measured. The important question which is not addressed by such studies is: when is compliance the result of legal threats, and when is it the result of other factors?

⁵ If Andenaes set the conceptual precedent, the empirical prototype can be found in the pioneering work of Gibbs (1968) and Tittle (1969). These two studies set the pattern for subsequent research by specifying criminal behavior as the dependent variable. Indeed, the title of Tittle's paper ("Crime Rates and Legal Sanctions") neatly summarizes—albeit in reverse causal order—what is usually taken as the deterrence hypothesis in its null form.

Table 1. Inferring Deterrence from Incidence of Offenses/Offenders: Hypothetical Data *

Category	A	B	C	D
1.	800	600	600	600
2.	100	200	150	250
3.	75	150	175	100
4.	25	50	75	50
Total	1000	1000	1000	1000

* The hypothetical data presented here are meant to depict non-experimental, cross-sectional data.

Legend: Category 1. Number of nonviolations/nonoffenders where extralegal factors produced compliance with law.
 2. Number of nonviolations/nonoffenders where legal threats produced compliance with law.
 3. Number of offenses/offenders which are undetected.
 4. Number of offenses/offenders which are detected.

is why, apparently, deterrence may be regarded as "inherently unobservable and hence immeasurable" (Gibbs, 1975:13).

These considerations are illustrated in Table 1 with hypothetical data. The total audience for the legal threat is divided into groups of nonoffenders or nonviolations (categories 1 and 2) and offenders or offenses (categories 3 and 4). The distinction between categories 3 and 4 represents the difference between "hidden deviance" and "officially known deviance" (the crime rate). Persons in category 1 are inhibited from crime by something other than the threat of legal sanctions.⁶ Category 2 includes those acts or actors that are deterred by threat of legal sanctions; here, extralegal controls have not inhibited criminal behavior, but legal threats have been able to do so.

⁶ Zimring and Hawkins (1973: 120) speak of this group as being characterized by "the strongly socialized individual who will obey commands out of a desire to do right, quite independent of the specific consequences of wrongdoing." The behavior of these persons is uninfluenced by the threat of legal sanctions, except perhaps indirectly, when their values are reinforced by the law. This group, however, is inhibited by factors such as moral sentiments, a simple distaste for the behavior, or the fear of other extralegal consequences from the prohibited behavior.

The hypothetical data have been ordered to extend over four separate time periods, denoted by A, B, C and D. This diachronic example illustrates a situation where the incidence of offenses has increased in each of the three time periods subsequent to time A. An increase of this nature commonly would be attributed to the depreciating deterrent efficacy of the legal sanctions attached to that offense. While this certainly is one interpretation, it is hardly the only one, as the data show. Columns A and B indicate a change in all four categories. When categories 3 and 4 are combined, they illustrate an increase of 100 in the total incidence of crime. However, category 2 also increased by 100, denoting that more cases are being deterred. This particular increase occurs because of a reduction of cases in category 1. Thus, a group whose behavior was previously constrained by extralegal factors is now potentially criminal and, hence, "eligible" for deterrence.⁷ Therefore, even though the incidence of offenses increased, there was a concomitant and equal increase in the *absolute*⁸ deterrent effect, as shown in the increase in category 2. The *net* deterrent effect is calculated by combining categories 3 and 4

⁷ It should be noted that this may be precisely what is happening with respect to marijuana use in the United States. Although the numbers in category 1 for the crime of homicide (a large number, given the strong moral and personal barriers to this offense) and for parking violations (a small number, since there are few moral barriers to the behavior) might be expected to remain relatively constant, there are a number of borderline offenses where moral sentiments can, and do change, independent of changes in legal status. While the numbers in category 1 might be decreasing for marijuana use, other offenses might be showing an increase, such as white-collar and corporate crimes, including environmental and consumer fraud offenses.

⁸ The *net* deterrent effect of a particular sanction can be defined as the total number of threatened behaviors the penalty inhibits less those it fails to inhibit. This definition differs slightly from that of Zimring and Hawkins (1973: 71) who define net deterrence in terms of the numbers of threatened behaviors the penalty prevents less those it creates. While this latter definition may be useful for some purposes, it is felt that the important consideration is the law's ineffectiveness rather than its "labeling" effect. The *absolute* deterrent effect is the number of threatened behaviors the penalty prevents without regard to those it fails to prevent.

and comparing this figure with that in category 2. This net result is 0 (an increase of 100 in incidence, balanced by an equal increase of 100 in absolute deterrence). Consequently, although an increase in incidence is observed, there is also an increase in absolute deterrence. The net result, of course, is *no change* in deterrent efficacy. By performing similar calculations with figures in the remaining columns, parallel conceptual points can be seen. Thus, calculations with columns A and C show a *net loss* of deterrent efficacy, while columns A and D show a *net gain*.

Thus, although each of the three situations shows an increase in the incidence of crime from time A, this information alone does not indicate the actual amount of deterrence because the group where deterrence occurs is not represented in the incidence of crime. Similar conclusions would be drawn if the data were reconstructed to show a decrease in crime. Therefore, knowledge that the incidence of crime has changed does not necessarily lead to correct inferences about the deterrent efficacy of the legal sanctions attached to that behavior; it is inappropriate to infer the behavioral influences of nonoffenders from the actual behavior of offenders.

PERSPECTIVE AND METHOD

These considerations suggest some new directions for nonexperimental research on deterrence. First, such research could benefit from more fully elaborated and explicit theories of legal and extralegal sources of conformity. Since the threat of legal sanctions is only one possible source of compliance, it would be useful if this determinant were differentiated from others, both conceptually and empirically. The relationships between extralegal factors and compliance deserve investigation, not only to permit isolation of the deterrence "effect" but also because they represent basic features of social control. Second, such studies should look for deterrent effects in a more general population of offenders and nonoffenders. That is, deterrence should be investigated by examining a population of persons or

acts that includes both compliance and noncompliance. If evidence of deterrence is to be found, it will be found by examining deterrable acts or actors, not a population of offenders who, by definition, were not deterred.⁹ We have attempted to pursue these implications by formulating a preliminary model of compliance to criminal law that specifies several simple additive causal relationships suggested by prior research. The model postulates that compliance/noncompliance is determined by both legal factors (knowledge of law, legal threat, perceived certainty and severity of punishment) and extralegal factors (social support, social influence, attitudes and several social background characteristics).

Our exploratory test of this model involved a method that differed in some important respects from previous studies. The survey data we utilize contain respondent reports of criminal activity including reported reasons for its *nonoccurrence*. We are sensitive about the obvious problems associated with interpreting self-reported criminal activity, and we recognize the arguable utility of respondent accounts of their own motivational states. For now, however, we are willing to tolerate these potential shortcomings in order to pursue certain conceptual and empirical alternatives to conventional deterrence studies.

The substantive focus of this test is on one criminal offense, a criminal statute for which there is widespread public ambivalence and which is widely violated: possession and use of marijuana. This focus on marijuana crime seems to us an especially appropriate context for examining the relative effects of legal and extralegal controls. Unlike other crimes, the marijuana offense may be expected to involve more variance in terms of its occurrence and in terms of the social distribution of its offenders. This greater variability makes it analytically less difficult to establish relationships in the context of our model. Moreover, the marijuana offense has been

⁹ A similar point has been made by van den Haag (1969) for the crime of homicide and the sanction of capital punishment. See also Zimring (1971: 18-9) for a discussion of this confusion.

said to be one of those criminal offenses where one might expect to find more evidence of deterrence compared to other crimes (Waldo and Chiricos, 1972).

Data utilized in this study were collected by Response Analysis Corporation as part of a national survey conducted for the National Commission on Marijuana and Drug Abuse (1972). The data were gathered in 1971 via personal interviews and self-administered questionnaires within a national probability sample of adults, age 18 and over; these procedures resulted in a weighted *N* of 632. A technical discussion of the sampling field and weighting procedures is provided by Abelson et al. (1972). The data presented here were obtained from respondents in Cook County (Chicago), Illinois, which was oversampled.¹⁰ At the time of the data collection, Cook County was governed by comparatively severe statutory penalties for the use of marijuana (depending on the amount, penalties for possession provided for life imprisonment in the extreme); one might thus expect that legal threats would be a relatively important social control in this area, at this time.

The dependent variable—reported marijuana use/nonuse—was coded into a three-category index based on self-administered questionnaire items: (1) marijuana “never-users”; (2) marijuana “ever-users,” persons who have used marijuana, but not in the past two years; (3) marijuana “current-users,” persons who were using marijuana at the time of the data collection. The measure of use/nonuse is an ordinal level variable which is treated as interval for purposes of this analysis.¹¹

Four classes of independent variables are examined: legal factors, social support

factors, background factors and selected attitudinal factors. Five indicators of legal factors were developed; two of these pertain to *statutory knowledge*. These variables were measured by asking the respondent if he or she knew about federal and state laws prohibiting marijuana use. Responses were dichotomized into yes (or think so) and no. *Perceived certainty* of punishment was measured by asking respondents, “How strictly are marijuana laws enforced in this community?” Responses were coded either as (1) not enforced very strictly or (2) strictly enforced. *Perceived severity* of punishment was measured by asking respondents, “How severe are the courts in this community for this offense?” Responses were coded (1) not strict enough, (2) about right or (3) too strict.

Legal threat was measured by asking the nonusing respondents to indicate the reason(s) for their nonuse. Twelve response alternatives were available, and those respondents who mentioned either “fear of arrest” or “fear of jail” were regarded as having identified a legal threat. All nonusing respondents were given a score of 2 (both items identified), 1 (one of them identified), or 0 (neither item identified). A confirmatory factor analysis, not reported here, justified these procedures.

We developed two measures of social support for marijuana use. One indicator, *number of friends*, was measured by asking respondents how many of their friends use marijuana, at least once in a while. Four categories of response were coded: none, almost none, less than half and more than half. A second social support indicator, *significant other pressure*, was derived from the question about the reason(s) for nonuse discussed earlier. When respondents designated “pressure from family” and “pressure from friends,” they were given a score of 2 (both items identified), 1 (one item identified) or 0 (neither item identified).

Seven background indicators were analyzed: age, gender, race, education, occupation, income and religiosity. *Gender* was dichotomized. *Race* was coded white or nonwhite. *Age* was coded as a six-category ordinal variable: (1) 18 to 25;

¹⁰ We also tested this model on two other jurisdictions, a low penalty area (Omaha, Nebraska) and a penalty area intermediate between Cook County and Omaha (Washington, D.C.). The results of these other applications are not presented here, partly for reasons that will become clear shortly.

¹¹ Labovitz (1967; 1970) has demonstrated that this is not a serious violation of assumptions and, in fact, should be done when one can assume a monotonic relationship between the measurement scale and the underlying scale. Moreover, regression analysis has proven itself a particularly robust technique with these measurement procedures.

(2) 26 to 34; (3) 35 to 39; (4) 40 to 49; (5) 50 to 59; (6) 60 years and older. *Educational level* is a five-category ordinal variable: (1) 8th grade or less; (2) some high school; (3) 12th grade; (4) some college; (5) college graduate or beyond. *Occupation* is a nine-category variable: (1) laborer; (2) farm; (3) service; (4) operative; (5) clerical; (6) craftsman/foreman; (7) sales; (8) managerial, official, proprietor; (9) professional and technical. *Income* was coded into eight categories: (1) under \$2,000 to \$2,999; (3) \$3,000 to \$4,999; (4) \$5,000 to \$6,999; (5) \$7,000 to \$9,999; (6) \$10,000 to \$14,999; (7) \$15,000 to \$24,999; (8) \$25,000 and more. *Religiosity*, measured in terms of frequency of church attendance, was coded: (1) not at all; (2) once in a while; (3) sometimes; (4) regularly.

Two additional variables were developed from responses to the question requesting reasons for nonuse. *Fear of physical consequences* from using marijuana was tabulated in three categories: fear of damage to body, fear of damage to mind and fear of becoming an addict. This variable was coded according to the number of relevant responses indicated. A second variable was based on whether respondents either did or did not cite as a reason for nonuse the *belief that marijuana use was an immoral activity*. The intercorrelations among the measured variables are shown in Table 2.

Our analysis employed multivariate regression and correlation techniques since regression analysis is especially well-suited for multiple factor issues (Tullock, 1974). The model we employ is relatively crude by some standards, but it seems to be a natural starting point for the model-building process. In this respect, the observation of even weak relationships between the legal and extralegal factors and compliance to marijuana laws may stimulate consideration of certain intervening variables and the question of direct and indirect effects (Hauser, 1976). We view marijuana use/nonuse as the dependent variable with four blocks of independent variables. First, we examine the simultaneous effects of all four blocks of independent variables; then the analysis is conducted separately for each block.

FINDINGS

Table 3 shows the standardized, partial regression coefficients for marijuana use/nonuse on all independent variables taken together, as well as by legal and extralegal blocks. The organization of the predictor variables into blocks was not only sensible conceptually, but also was performed to reduce the problem of redundancy (Gordon, 1968) which is associated with analyses that involve a large number of predictor variables. Some coefficients are small because of certain metric decisions whereby interval measured variables are coded as categorical.

The data show, first of all, that despite the measurement problems, the model accounts for a large proportion of the variance in marijuana use/nonuse in this jurisdiction; the total sum of squares (R^2) explained by the model is 72%. Examination of the coefficients, however, indicates that the predictability of marijuana use/nonuse is a function of only a few variables. Thus, the number of friends who use marijuana is the best single predictor ($\beta = .780$). From the sign of the coefficient, the influence of friends' use on respondents' use/nonuse is probably a reinforcing rather than a controlling effect. The central focus of this analysis, however, is not so much the general predictability of marijuana use/nonuse but, rather, the relative contribution of legal and extralegal factors to it. Attention now turns to these effects.

Legal factors. The block of legal variables accounts for 12% of the variance in marijuana use/nonuse, but this effect largely is produced by one variable, perceived severity of marijuana statutes ($\beta = .348$). Although this variable has the strongest effect, the direction of the coefficient is the opposite of what would be expected from the deterrence hypothesis, with the data showing that with increasing perceived severity of these penalties, use of marijuana increases. We have checked and rechecked these data for errors and find none. Our initial interpretation was simply that users were more likely than nonusers to know about the relatively high penalties in Cook County.

* Coefficient of Determination corrected for degrees of freedom.

But, after examining the relationship between these same variables in other jurisdictions with milder penalties, we were persuaded that this particular question probably tapped the sense of moral outrage and injustice that marijuana users attribute to these laws in general. Perceived certainty of punishment, on the other hand, shows essentially no effect on marijuana use/nonuse which, again, is contrary to what we had expected and is inconsistent with previous research on this offense (see Waldo and Chiricos, 1972).

The most noteworthy finding, however, is the noncontributory nature of the indicator of legal threat. This variable's coefficient ($\beta = -.040$) shows a measurable, but essentially trivial influence on marijuana use/nonuse. When legal threat is examined jointly with all other predictor variables, the coefficient is slightly larger ($\beta = .180$), reflecting a relationship (Table 2) with physical fear ($r = .35$) and with significant other pressure not to use marijuana ($r = .35$) and with significant other pressure not to use marijuana ($r =$

.40). Although legal threat exerts no appreciable direct effect, it appears to indirectly affect use/nonuse through other variables.

Extralegal Factors. The social background variables, as a block, account for 21% of the variance in marijuana use/nonuse; the largest effects are associated with age ($\beta = -.407$) and occupation ($\beta = .156$). The strong influence of age is consistent with an interpretation that treats age as a proxy for varying degrees of commitment to the conventional social order (e.g., Hirschi, 1969).

Of all extralegal variables, social support generates the strongest effect on marijuana use/nonuse ($R^2 = .66$). Again, the influence of number of marijuana-using friends is striking ($\beta = .812$).

The belief that marijuana use is immoral ($\beta = -.168$) and the perceived physical consequences of using marijuana ($\beta = -.247$) together account for 10% of the variance in marijuana use/nonuse, and the signs of the coefficients suggest that each factor functions to inhibit marijuana use. These two factors, as indicated earlier,

are positively correlated with legal threat, which further suggests that these three factors jointly may inhibit marijuana use.

In summary, the data pertaining to the relative influence of legal and extralegal factors on marijuana use/nonuse suggest that legal threat is a comparatively important source of compliance. Legal factors generate some explanatory power, but most of this influence appears to be indirect. Compared to other variables, the legal block is relatively unimportant. The factors—legal or extralegal—that appear to functionally inhibit marijuana use are age, fear of physical consequences of such use, and beliefs that marijuana use is immoral.

SUMMARY AND DISCUSSION

In preceding sections, we argued that contemporary deterrence research might profit by pursuing certain new conceptual and empirical directions. We recommended that the concept of deterrence be anchored in, and integrated with, certain principles associated with the social influence-compliance and social control literature and, especially, with prior research pertaining to the mechanisms of threat. We also argued for conceptualizing deterrence more broadly to include a variety of legal and extralegal factors which ultimately may be included in a general model of social control.

In reviewing certain problems associated with prior nonexperimental tests of the deterrence effect, we observed that the traditional use of official crime statistics is not only misleading but probably irrelevant to identifying the conditions under which legal threats actually deter. As an alternative focus, we suggested that deterrence research examine the circumstances and experiences of nonoffenders—the criminally compliant. Finally, after constructing a preliminary model of social control, we presented the results of an exploratory test. We recognize that we have not developed a fully specified theory of social control, particularly one that considers the effect of simultaneous or reciprocal influence among the variables. We also recognize that our preliminary application of the

model, using self-report data pertaining to marijuana use or nonuse as well as respondent reports of reasons for non-use, may be challenged in terms of the well-known measurement effects produced by response error. In our view, these possible shortcomings are offset by the need to explore conceptual and empirical alternatives in understanding the deterrence process.

Our empirical alternative may raise other questions. First, although the data presented provide little support for the deterrence hypothesis as ordinarily formulated, we found that marijuana use or nonuse is a relatively orderly or, at least, predictable phenomenon. That is, we found substantial evidence of social control-compliance produced by ordinary and extralegal processes and influences. The findings suggest the importance of age-graded norms, and this interpretation seems generally consistent with traditional sociological arguments concerning the relative efficacy of informal versus formal social control mechanisms. In this regard, despite contemporary predisposition toward the importance of legal sanctions, our findings are at least consistent with the accumulated literature concerning the primacy of interpersonal influence.

A second question that may be raised pertains to the suitability of marijuana possession or use as an appropriate test of deterrence. We have encountered two general objections to testing a deterrence model with marijuana crime. First, there is currently an inclination to relegate marijuana crime to the gray area of deviance; marijuana use is no longer viewed as “really” criminal and, hence, it is thought to be an inappropriate activity for testing deterrence hypotheses. Although we do not argue with the fact of apparent changing social definitions of marijuana use, we also do not subscribe, on an *a priori* basis, to the viewpoint that it is different in kind from other crimes. At the time the data reported in this study were collected, marijuana offenses were still defined as criminal and a substantial number of marijuana arrests were made in the jurisdiction(s) examined. In this regard, the marijuana possession statute was not a “dead letter” law, although its

enforcement was selective and perhaps uneven. In any case, marijuana crime is behavior that was still vulnerable to the application of criminal sanctions upon detection at the time these data were collected.

Still another matter concerns the apparent inconsistency between the findings produced here and the comparative study of deterrence in marijuana and theft offenses by Waldo and Chiricos (1972). The Waldo and Chiricos study compared the relative deterrent efficacy of the laws governing two crimes, one with substantial social support (theft) and one with considerably less support (marijuana use). This research addressed the contention that for offenses that are widely practiced or condoned, legal threats produce more conformity because the law "stands alone"; it was hypothesized that compliance to marijuana statutes was less likely to be a function of extralegal influences (Andenaes, 1974; Zimring, 1971: 44-5). Waldo and Chiricos found that marijuana use was more likely than theft to be deterred, and they interpret this to indicate that the law is relatively more effective (by default) given the absence of other influences on behavior. The data presented here do *not* support the contention that the law stands alone for marijuana; instead, we found that certain extralegal factors not only influence marijuana use and nonuse, but exercise a stronger effect than do legal factors. We also wish to emphasize that the jurisdiction to which these data pertain had relatively severe penalties at the time of data collection.

The single jurisdictional focus of this analysis may suggest questions concerning the generalizability of these findings. In this regard, we should report that the model presented also has been tested with data from two other jurisdictions with different statutory penalties, Omaha, Nebraska, and Washington, D. C. These analyses showed that the relative impact of the variables examined was generally similar; we also found differences, however, in the coefficients for specific contributions of certain variables, although we presently are unable to account fully for these jurisdictional differences (in-

teractions) short of invoking a "jurisdictional effect," a practice we wish to avoid.

Finally, and in light of the caveats mentioned, we wish to emphasize that the results of this application of deterrence theory would not have been identified nor appropriately interpreted within the more conventional deterrence research paradigm. It is essentially this contrast that persuades us that traditional formulations of the deterrence effect require conceptual scrutiny and the consideration of alternative methods. It is essential that we explore new research directions that conceptually anchor the deterrence effect among other mechanisms of social control and empirically focus on the relevant population parameters of noncompliance and compliance.

THE DETERRENCE DOCTRINE AND THE PERCEIVED CERTAINTY OF LEGAL PUNISHMENTS*

MAYNARD L. ERICKSON

JACK P. GIBBS

GARY F. JENSEN

University of Arizona

American Sociological Review 1977, Vol. 42 (April):305-317

This research on the deterrence doctrine differs from previous investigations by focusing on perceived properties of legal punishments rather than objective properties. Data from a survey of 1,700 high school students in Arizona show a close inverse relation among 15 types of crimes or delinquencies between the median or mean perceived certainty of punishment (arrest or reformatory) and rates of self-reported acts. However, the same relation holds between the rates and the perceived seriousness of acts, which is taken as indicative of the social (extra-legal) condemnation of crime. Furthermore, the perceived certainty of punishment and perceived seriousness are so highly collinear that their effects on the rates cannot be differentiated. Although the findings cannot be viewed as conclusive evidence against the deterrence doctrine, they raise doubts about previous interpretations of the inverse relation among states between the objective certainty of imprisonment and crime rates. The relation has no bearing on the perceptual assumptions that enter into the deterrence doctrine, and the present findings indicate that the relation could reflect differential social condemnation of crime.

In reconsidering the deterrence doctrine, investigators have not emphasized that the subject touches on larger issues in sociology. A fair reading of Bentham (1962) and Beccaria (1963) clearly reveals that the deterrence doctrine is a *psychological* theory. To be sure, a penal system is social; but unless deterrence is defined in psychological terms, the definition is alien to Bentham's or Beccaria's conceptualizations and extends the meaning of deterrence to virtually any action by legal officials that prevents crimes by one means or another (e.g., incapacitation). A narrow definition of deterrence (e.g., Bedau, 1970) is more in keeping with Bentham or Beccaria, and the terms (fear, perceived risk, pain) employed in those definitions denote psychological phenomena.

The most obvious implication of such definitions is that perceptual variables must be taken as paramount in testing the deterrence doctrine. Briefly, the doctrine reduces to the assertion that when a crim-

inal act is contemplated the *perception* of a high risk of a swift and severe reaction by legal officials is a *sufficient* condition for omitting that act. If that brief version of the doctrine is accepted, then an empirical relation between objective properties of punishment (e.g., the proportion of alleged crimes that actually result in the arrest and/or imprisonment of a suspect) and the crime rate is *at most* only a necessary condition for corroboration of the deterrence doctrine.¹ So commentators have rightly criticized deterrence investigations for their exclusion of perceptual variables (see especially Geerken and Gove, 1975; Gibbs, 1975; Henshel and Silverman, 1975).

Although perceptual considerations are truly central in the deterrence doctrine, sociologists who work in the Durkheimian tradition have no enthusiasm for theories that deal with psychological phenomena. Yet some sociologists (e.g., Homans,

* This paper is based on data gathered as part of a larger study of "Community Tolerance and Measures of Delinquency" supported by a grant from the National Institute of Mental Health (MH22350). The authors express their gratitude to the entire staff and especially to Mark Stafford for his work in analyzing the data.

¹ A truly narrow interpretation of the deterrence doctrine would assert that the objective properties of legal punishment are irrelevant, meaning that the doctrine is a purely *perceptual* theory. Yet both Bentham and Beccaria evidently believed that objective properties are relevant (though their statements along that line are obscure); moreover, without that supposition the deterrence doctrine has no policy implications.

1974) are predisposed to such theories, and the contrast in preferences appears irresolvable. In any case, a preference for some kind or level of theory is one issue, while the assessment of the empirical validity of a particular theory (whatever the kind or level) should be recognized as a separate issue. The point is that sociologists who prefer macroscopic or structural-functional theories are correct if they identify the deterrence doctrine as alien to their interest, but that identification has no bearing whatever on the empirical validity of the deterrence doctrine. Yet it does not follow that psychologically-oriented sociologists necessarily accept the deterrence doctrine. They may object to the doctrine by alleging that it assumes rationality or free will (e.g., Schuessler, 1952); but defenders of the doctrine (see especially van den Haag, 1969; Jeffrey, 1965) question those allegations and suggest a completely opposite interpretation—that the doctrine is thoroughly deterministic.

Basic Alternative Strategies for Deterrence Research

There are at least three basic strategies for nonexperimental research on general deterrence: (1) an examination of the relation between properties of punishment and crime rates *among jurisdictions*, (2) an examination of the relation *among types of crimes* in the same jurisdiction, and (3) an examination of the relation between perceived properties of punishment and the frequency of criminal acts *among individuals*.² Even if one should argue that only the third strategy (comparisons of individuals) can provide definitive evidence, the other two are surely relevant. However, most purported tests of the deterrence doctrine at the aggregate level have been restricted to comparisons of jurisdictions (e.g., states of the U. S.). While that limitation may not be as serious as the exclusion of perceptual variables, evidence concerning deterrence is incomplete without the second research

strategy—that is, comparisons of types of crimes.

With a view to expanding the range of evidence on the deterrence doctrine, the research reported here focused on a comparison of types of criminal or delinquent acts as regards (1) the perceived certainty of punishment and (2) the estimated incidence of the act. As such, the research differs from previous investigations in that types of acts rather than jurisdictions are units of analysis and the perceived certainty of punishment rather than the objective certainty is the principal independent variable.

The Perceived Certainty of Punishment

Although various perceptual properties of punishment are seemingly relevant in testing the deterrence doctrine (Gibbs, 1975), the present focus on *perceived certainty* is justified by two considerations: first, numerous statements by Beccaria and Bentham suggest that the certainty of punishment is more efficacious (as regards deterrence) than is the severity of punishment; and, second, the emphasis on certainty is entirely consistent with the findings of recent investigators, most of whom report that *among states* the crime rate is much more inversely related to the objective certainty of imprisonment than to the presumptive severity (length) of prison sentences (see surveys by Tittle and Logan, 1973; Zimring and Hawkins, 1973; Silver, 1974; Gibbs, 1975). Those findings may be pertinent in assessing the relative deterrent efficacy of the certainty and severity of *actual* punishments, but it is dubious to construe the inverse relation between the certainty of imprisonment (or any kind of punishment, for that matter) and the crime rate as corroborating the deterrence doctrine. First and foremost, it is dubious not because of arguments about purely statistical artifacts (see Chiricos and Waldo, 1970; Logan, 1971; 1972) or even questions about the reliability of official crime rates. Rather, the evidence is disputable because of the very nature of the deterrence doctrine.

Granted that the deterrence doctrine is not a systematic theory (Gibbs, 1975), any reasonable interpretation would recognize

² Logan's research (1972) is an instance of the first kind of investigation, and Waldo and Chiricos' research (1972) is an instance of the third type.

that the doctrine encompasses at least two interrelated premises pertaining to differences (1) among jurisdictional populations as regards some type of crime or (2) among types of crime in the same jurisdiction.

Premise I: The greater the objective certainty of punishment, the greater the perceived certainty of punishment.

Premise II: The greater the perceived certainty of punishment, the less the crime rate.

The issue at hand is not the choice of a covariational rather than a causal language in stating the premises. Whatever the language, the objective certainty of punishment is asserted to be associated with the crime rate only through the perceived certainty of punishment. By the use of the sign rule and assuming that the relations asserted in the premises (I and II) are close, it is possible to deduce an assertion of an inverse relation between the objective certainty of punishment and the crime rate from the two premises. However, if the punishment is imprisonment, the same relation can be deduced from alternative premises.

1. The greater the objective certainty of punishment, the greater the incapacitation of potential repeaters.
2. The greater the incapacitation of potential repeaters, the less the crime rate.

The rationale for the alternative premises is scarcely less plausible than the deterrence premises, as no one is likely to deny that some crimes (e.g., auto theft) are a difficult achievement in prison. Accordingly, recent findings of an inverse relation between the objective certainty of punishment and the crime rate are, at most, only a *necessary condition* for corroboration of the deterrence doctrine, as the relation could obtain through incapacitation even if *both* deterrence premises (I and II) were patently false. The only way to bring less conjectural evidence to bear on the deterrence doctrine is by a direct

test of the premises, and the present paper reports such a test of Premise II: The greater the perceived certainty of punishment, the less the crime rate.

Data Employed in the Present Research

Previous deterrence investigations focused on the *objective* certainty of punishment because enormous resources would be required to gather data on perceptions of certainty in each of several jurisdictions. However, if the deterrence doctrine is tested by comparing types of crimes or delinquencies, data on the perceived certainty of punishment can be gathered by a survey in one jurisdiction.

Although comparisons of types of acts (crimes or delinquencies) are more feasible than jurisdictional comparisons, both strategies are questionable if the tests of the deterrence doctrine are based on official crime rates. Doubts about the reliability of those rates are legion. Accordingly, with a view to expanding the range of evidence on the deterrence doctrine, the present research compared types of acts in the same jurisdiction as to (1) the perceived certainty of punishment and (2) the number of acts reported by a sample of residents of the jurisdiction.

Data for juveniles. To obtain data for tests of the second deterrence premise, questionnaires were administered to 1,700 juveniles in six Arizona high schools, three in a metropolitan area and one each in three small Arizona towns. The students were asked several questions about legal punishment and their commission of criminal or delinquent acts.³ However, before considering the questions that are relevant for present purposes, three issues are considered.

In a literal sense, the deterrence doctrine makes assertions about crimes rather than delinquent acts by juveniles. How-

³ No sampling of students was attempted, which is to say that coverage was complete except for (1) some 10% of the students who were absent from school the day data were collected or (2) those who were not given parental permission to participate in the survey. The questionnaires were administered in group sessions, and each student made entries only after extensive instructions. The "codeable response rate" is no less than 90 percent for each item in the questionnaire.

ever, the distinction is dubious, especially if a strictly legal conception of delinquent acts is accepted. Delinquent acts are subject to punishment in much the same sense as are crimes; and the fact that individuals above some minimum age can commit criminal but not delinquent acts is not crucial, for all manner of "crimes" are peculiar to or contingent upon particular statuses. No less important, the laws of a jurisdiction may be such (as in Arizona) that juveniles who commit crimes are liable in *principle* to the same punishments as adults. So the argument is that tests of the deterrence doctrine can justifiably consider acts by juveniles, whether those acts are crimes or delinquencies.

The use of data pertaining to "self-reported crimes and delinquencies" raises an even more critical issue. Even though use of such data is now virtually a convention, the reliability and validity of the data are nonetheless subject to question (see Reiss, 1973). For any given body of self-reported data (crimes or delinquencies),

there is no truly defensible and feasible basis for identifying or estimating the proportion of respondents who (1) misunderstood the description or denotation of acts in the self-report questions, (2) did not remember having committed the act, or (3) deliberately gave an incorrect answer. Nonetheless, granted that there is no evidence that would justify any definite conclusions about the reliability of self-reported data on crimes or delinquency, it does not tax credulity to assume that self-reports are at least as reliable as estimates of the frequency of criminal or delinquent acts based on apprehension records or court records.⁴ The more general point is

⁴ The same arguments could be made for the use of "victimization" data. However, unlike self-reported data, victimization data cannot be used to test the deterrence doctrine by examining the relation *among individuals* between perceived properties of punishment and frequency of criminal or delinquent acts. The present data can be used to conduct such a test; but work along that line has not been completed, and space limitations preclude reporting even preliminary results.

Table 1. Questions Answered by Students in Six Arizona High Schools, 1974^a

Question ^b	Corresponding Legal Label
1. Take money or something by threatening someone with a weapon (gun, knife, etc.)?	1. Armed robbery
2. Steal something worth more than \$100 (<i>not counting shoplifting</i>)?	2. Grand theft
3. Take someone's car without their permission?	3. Auto theft
4. Take money or something from someone by just threatening them (without a weapon)?	4. Unarmed robbery
5. Beat up or hurt someone on purpose?	5. Assault-battery
6. Break into a place to do something illegal?	6. Burglary
7. Steal something worth less than \$100 (<i>not counting shoplifting</i>)?	7. Petty theft
8. Take something from a store on purpose without paying for it ("shoplifting")?	8. Shoplifting
9. Use any marijuana?	9. Marijuana use
10. Run away from home?	10. Runaway
11. Get into any fist fights or brawls (<i>not counting the times you beat up or hurt someone on purpose</i>)?	11. Fighting
12. Drink any beer, wine or liquor (<i>not counting sips your parents let you have</i>)?	12. Drinking
13. Disobey or defy your parents?	13. Defiance
14. Skip school without an excuse?	14. Truancy
15. Smoke or chew tobacco?	15. Smoking

^a Three schools in an SMSA and one each in three small-town high schools.

^b Each question was preceded by the phrase: "During the last 12 months, how many times did you..."

that tests of the deterrence doctrine necessarily employ data that are inherently questionable. So, at present, there can be no definitive tests of the deterrence doctrine, and the only hope is that various kinds of data on the incidence of crimes or delinquencies yield more or less the same results.

Questions posed. Table 1 shows each of the questions pertaining to self-reported acts and corresponding "legal labels" that are used in subsequent tables. Two measures of central tendency, the mean and the median, were used to describe the responses of students to each question. Those values are shown in columns 3 and 4 of Table 2 and, henceforth, they are referred to as "mean" or "median" acts. In recognition that for some types of crimes only a few students reported any commissions, still another "rate" was computed. It is simply the proportion of students who reported *at least one* commission of the offense and, hence, it corresponds to what Gibbs (1975) has designated as the "categorical rate." Those rates are shown in column 5 of Table 2.

In a subsequent section of the questionnaire, two additional questions were asked about each of the same 15 acts, with the acts described as in the first column of Table 1. The additional questions were worded as follows: "Out of the last 100 times a juvenile (*description of the act*): (1) How many would you guess resulted in an arrest? (2) How many would you guess resulted in a juvenile being sent to a state reformatory?" Answers to each question were analyzed as percentages (i.e., the base is 100) and they are taken as the perceived certainty of the designated type of legal reaction, either arrest or incarceration.⁵ Two "certainty values," the mean

and the median, are shown in Table 2 for each type of legal reaction (see columns 1-2 and 6-7). Henceforth, those values are referred to as "mean certainty" or "median certainty."

The frequency of crimes or delinquencies may reflect two conditions independent of the character of legal punishments, those two being the "extralegal inhibitory" and the "extralegal generative" (Gibbs, 1975). Those terms denote strictly logical possibilities; that is, they do not give rise to falsifiable generalizations about particular empirical correlates of crime or delinquency. Moreover, deviance theories are not such as to justify the identification of specific extralegal generative variables; but in the case of the extralegal inhibitory there is a longstanding, purely normative argument—that the frequency of a particular type of act in a population varies inversely with the social (extralegal) condemnation of that act. With that argument in mind, the students were asked a question about each of the 15 types of acts in the following form: "If the number 100 was used to indicate how serious stealing something worth less than \$100 is, what number would you give to (*description of the act*)?" The median value of responses (magnitude ratios) to the question for each type of act is shown in column 8 of Table 2. The use of medians for magnitude ratio data are now conventional (see Hamblin, 1974).

Needless to say, there are various ways that such a "seriousness" question could be worded (see, e.g., Sellin and Wolfgang, 1964; Rossi et al., 1974), with some of the alternative key terms being: disapprove, personally disapproves, bad, and disapproved by others. Only experimentation can reveal whether the wording of an evaluative question makes any substantial difference, but there is a rationale for the use of the key term "serious." It is the most general term possible, since it

the frequency of crime but also with the relation between objective and perceptual properties of legal punishment. In any case, the kind of perceptual variable (if any) that is related to the crime rate remains to be determined, and the deterrence doctrine cannot be construed as a testable theory until (*inter alia*) it is extended to a specification of the kind of relevant perceptions of the certainty of punishment and procedures for gathering related data.

⁵ Needless to say, the exact wording of such a perceptual question could make an appreciable difference in the outcome of tests, and some of the alternatives can be conceptualized. Rather than ask questions that pertain to perceived *aggregate* certainty, the questions could be worded so that they pertain to perceived *personal* risk of punishment. Although some commentators on deterrence research (e.g., Teevan, 1975) evidently presume that only perceptions of personal risk could be relevant, it is difficult to see how that can be known *a priori*, especially if investigators are concerned not only with the relation between perceived certainty and

^a See Table 1 for a more detailed description of the types of acts and see text for a description of the procedures employed in gathering the data.^b Proportion of respondents reporting one or more instances of the act.

suggests not only a personal evaluation of the act but also awareness of a collective evaluation (i.e., how others evaluate it).

Comparisons of Types of Acts

Table 2 reports all of the data needed for tests of the second premise of the deterrence doctrine, which asserts an inverse relation between the perceived certainty of punishment and crime rates. Specifically, the prediction is an inverse relation between each of the alternative measures of the perceived certainty of punishment (columns 1, 2, 6, and 7 of Table 2) and each of the alternative self-reported rates (columns 3–5 of Table 2).

Findings on the perceived certainty of arrest. Regardless of the alternative measures of the two variables or the division of the student population considered (metropolitan versus small town), all correlation coefficients in column 1 of Table 3 are consistent with the second deterrence premise. However, the degree of association is clearly relative to the type of self-reported rate, with the correlation consistently greater for the categorical rate.

The differences among the correlation coefficients within each panel of column 1 (Table 3) reflect nonlinear relations between the perceived certainty of arrest and the mean or median frequency of self-reported acts. Specifically, when the data are plotted in a scatter diagram with certainty values on the horizontal axis and the mean or median acts on the vertical axis, the form of the relation is negative logarithmic;⁶ hence, the log correlations (column 6, Table 3) tend to be greater than the linear correlation (column 1, Table 3). The log correlations also vary much less than the linear correlations (compare columns 1 and 6 in *each panel* of Table 3), which indicates that the substantial variation in the linear correlations (column 1 within each panel) is due to extremely

high self-reported rates for particular types of crimes or delinquencies. However, relatively extreme values are more conspicuous for the median or mean frequency of acts (especially the mean) than for the categorical rate; therefore, only in the case of the categorical rate is the linear correlation greater than the log correlation.

The difference between the categorical rate and the other measures of the frequency of self-reported acts takes on theoretical significance in connection with types of deterrence. The findings suggest that if the correlations are manifestations of deterrence, the type is "absolute deterrence" (see Gibbs, 1975), which has to do with the distinction between individuals who have never committed the act and those who have committed it at least once.⁷ The categorical rate corresponds to that distinction, while the mean number of acts is a version of the conventional crime rate, that is, the number of offenses as a ratio to the *total* population (those individuals who have never committed the acts *and* those who have). However, the argument is not that the findings somehow demonstrate absolute deterrence. A large proportion of individuals who have never committed a particular type of criminal or delinquent act is only a *necessary* condition for *inferring* substantial absolute deterrence. Some individuals may never so much as contemplate the type of act in question; and of those who do contemplate it, some may refrain in recognition of the social condemnation of the act and/or the possibility of extralegal sanctions. That consideration makes the perceived seriousness values in Table 2 relevant in the present analysis.

As shown in column 4 of Table 3, the relation between the perceived certainty of arrest (mean or median values) and the frequency of self-reported acts (mean, median, or categorical rate) is quite different when the seriousness values of acts are partialled. All of the partial correla-

⁶ That is, beyond some point any further increase in the perceived certainty of punishment is associated with only very small decreases in the mean number of self-reported acts. The form of the relation may largely reflect a "floor effect" (i.e., the number of self-reported acts cannot be negative) and the fact that for several types of acts the modal self-reported number is zero.

⁷ Given an individual who has never committed a particular type of crime but one who has contemplated it and refrained out of fear of punishment at least once, that individual is an instance of absolute deterrence (relative to the type of crime and some point in time).

tions are negligible, with no more than 17 percent of the variance in the frequency of self-reported acts explained by variance in the perceived certainty of arrest. Those partial correlations reflect two relations: (1) a very close direct relation between the seriousness of acts and the perceived certainty of arrest, as shown in column 3 of Table 3; and (2) a substantial inverse relation between the seriousness of acts and frequency of acts, as shown in column 2 of Table 3. The effect of partialling seriousness cannot be attributed to the previously noted nonlinear relations, since the same effect obtains when the log correlations are considered (see column 9 of Table 3). Indeed, in that case, partialling even more dramatically diminishes the relation between the perceived certainty of arrest and the frequency of self-reported acts.

On the whole, the foregoing summary observations apply in much the same way to both major divisions of the student population, that is, metropolitan and small-town high schools. The similarities are noteworthy since it is virtually an article of faith among commentators on the deterrence doctrine (e.g., Zimring and Hawkins, 1973) that some populations are more deterrable than others. That may be so, but the present findings suggest that deterrability is not invariantly associated with the rural-urban distinction.

Perceived certainty of incarceration. Table 4 is exactly like Table 3 except the perceived certainty values that enter into the correlations pertain to "being sent to a state reformatory" rather than to arrest. Although the outcome of tests of deterrence propositions could be contingent on the type of legal punishment, that is clearly not the case for the present findings. With two exceptions, *all* of the observations and interpretations of the coefficients of correlation in Table 3 apply to those in Table 4.

The most obvious exception has to do with the effect of partialling the seriousness of acts when examining the relation between the perceived certainty of punishment and the frequency of self-reported acts (crimes and delinquencies). There is one set of partial correlation coefficients in which most of the coefficients

are negative and substantial. That one set comprises the partial log correlations for small-town high schools (see column 9 of Table 4, bottom panel). At least four of the six correlation coefficients *appear* to represent support for the second premise of the deterrence doctrine even though the seriousness of acts is partialled.

The second exception has to do with the difference between measures. One of the log partial correlation coefficients in *each* panel of column 9 (Table 4) is negative and substantial by any reasonable standard, and those coefficients pertain to the relation between the *median* perceived certainty of incarceration in a reformatory and the *median* self-reported rate.

A declaration that either of the two exceptions is convincing evidence in support of doctrine would be most disputable. There is nothing in any version of the deterrence doctrine that would anticipate positive test results only for the small-town population, and that is all the more the case since even for that population positive test results obtain only for log correlations. Positive test results are not peculiar to one population if only the median values of the two variables are considered; but there is no theoretical rationale for identifying those particular measures as crucial, let alone why they provide support for the deterrence doctrine only in the case of log correlations.

Even if there were a theoretical rationale for anticipating positive tests of the second deterrence premise only for particular kinds of measures of crime and/or particular kinds of populations, there would still be the problem of accounting for the differences between Tables 3 and 4. Whereas the partialling of seriousness of acts virtually eliminates the inverse relation between the perceived certainty of *arrest* and self-reported rates regardless of the kind of measures or population (see Table 3), that is not the case for the inverse relation between the perceived certainty of *incarceration* and self-reported rates (see Table 4). Defenders of the deterrence doctrine may reason that the contrast is consistent with a conventional belief about deterrence—that the certainty of punishment is important only to the extent that the punishment

^c Proportion of students who reported committing the act one or more times.

is severe. While incarceration in a reformatory is undoubtedly perceived as more severe than arrest, the argument in question is not consistent with the zero-order correlations (linear or log) in Tables 3 and 4. Specifically, it simply is not the case that the inverse relation between the self-reported rate and the perceived certainty of punishment is closer when the punishment is incarceration rather than arrest. True, it could be that the relation is contingent on the severity of the punishment when the social condemnation of crime is constant (i.e., seriousness of acts is partialled), but that possibility is not even suggested by any version of the deterrence doctrine. The more general consideration is that the statement of the deterrence doctrine as a sophisticated theory may be far more difficult than any version of the doctrine suggests.

Contrary interpretations of the test findings. Since the zero-order correlation coefficients in columns 1 and 6 (linear and log) of both Tables 3 and 4 are consistent with the second deterrence premise, the issue hinges largely on the results obtained when the seriousness of acts is partialled. Defenders of the deterrence doctrine cannot justifiably dismiss the partials on the grounds that the values representing the perceived certainty of punishments and the frequency of self-reported acts are unreliable, for the same data enter into the zero-order correlations that *are consistent* with the second deterrence premise. Alternatively, defenders of the doctrine can focus on the close direct relation between the seriousness of acts and the perceived certainty of punishment (see columns 3 and 8 in Tables 3 and 4), for when that relation is controlled the correlation between the perceived certainty of punishment and the frequency of self-reported crimes or delinquencies is not consistently substantial.

One argument is that individuals tend to view a type of crime or delinquency as "serious" only to the extent that they perceive the legal punishment of it as certain, and the argument extends to the claim that perceptions of legal punishment generate or maintain the social condemnation of crime. Yet there is no systematic evidence on the nature of the relation be-

tween the perception of punishment and variables pertaining to the extralegal evaluations of types of crimes, such as the present "seriousness" values. Although defenders of the deterrence doctrine may argue that perceptions of legal punishment for a type of crime as "certain" lead individuals to view that crime as serious, the opposite argument is scarcely less plausible. Specifically, it may be that individuals tend to perceive the certainty of punishment in terms of "what ought to be"; that is, legal punishment of serious crimes *should be certain*. The argument is all the more plausible since it is difficult to see how the typical individual has a sufficient experiential basis for even relatively accurate estimates of the certainty of punishment. Nonetheless, conventional versions of the deterrence doctrine clearly assume a relation between perceptual properties and objective properties of punishments, perhaps because without such a relation the doctrine would have no implications for penal policy.

Even if it is granted that the perceived seriousness of crimes or delinquencies is a function of the perceived certainty of legal punishment, there is still the question of the inverse relation between perceived seriousness and the crime-delinquency rates (see columns 2 and 7 in Tables 3 and 4). That relation also enters into what has been construed as negative test findings (i.e., the partialling of seriousness values), but defenders of the deterrence doctrine can make an argument about the relation.

If perceived seriousness of criminal or delinquent acts is a function of the perception of legal punishment and if individuals refrain from a particular act to the extent they perceive it as serious, then the crime rate is an *indirect* function of perceptions of legal punishment. However, even granting such an argument, the function of punishment is no longer deterrence but normative validation (Gibbs, 1975), meaning the generation and/or maintenance of the social (extralegal) condemnation of crime. Surely there is some significance in the difference between (1) an individual refraining from a criminal or delinquent act out of fear of legal punishment and (2) an individual refraining from or not even contemplating such an act because he or

she condemns it. The difference is significant even if prescribed or actual legal punishments somehow maintain the condemnation of crime. Nonetheless, as a last resort, defenders of the deterrence doctrine can argue that normative validation is only a secondary function of legal punishment, meaning that variation in the crime rate largely reflects the direct effects of deterrence. That argument is scarcely incredible, but it goes far beyond any existing data.

Whatever the plausibility of the contending arguments, the present data offer no basis for resolving them. It is the familiar problem of collinearity, in this case a very close direct relation between the perceived certainty of punishment and the seriousness of types of acts. Hence, as shown in Tables 3 and 4, when the perceived seriousness of acts is partialled, the relation between the perceived certainty of punishment and the frequency of self-reported crimes or delinquencies becomes negligible; but when the perceived certainty of punishment is partialled, the relation between seriousness of acts and the frequency of self-reported acts becomes negligible. Since one partial correlation cannot be justified to the exclusion of the other, the findings cannot be taken as conclusive evidence for or against the deterrence doctrine.

Nonetheless, the findings clearly cast doubts on the deterrence doctrine, or at least on one of its premises. *Until defenders of the doctrine show that the relation between properties of legal punishments and the crime rate holds independently of the social condemnation of crime*, then all purported evidence of general deterrence is suspect. In that connection, previous tests of the deterrence doctrine through interstate comparisons not only ignored perceptual variables but also failed to control for the social condemnation of crime.

Of course, the deterrence doctrine can be restated to stipulate the *kinds* of conditions in which deterrence operates independently of or is more important than social condemnation as a determinant of the crime rate. A comparison of columns 9 and 10 in Table 4 suggests one such condition. In several instances, the inverse relation between the perceived certainty of

punishment and the crime rate remains substantial when the perceived seriousness of acts is partialled, but the inverse relation between the rate and perceived seriousness disappears when perceived certainty of punishment is partialled. Observe, however, that such contrasts in the partial correlation are contingent on (1) the kind of measures (e.g., mean or median), (2) kind of values (log or absolute), (3) kind of punishment, and/or (4) kind of population. Moreover, even if the findings do show that deterrence operates independently of or is more important than the social condemnation of crime in some instances, no set of instances constitutes a generalization, let alone a theory.

Implications for Interpretation of Previous Findings

This research has considered only the perceived seriousness of types of crime as a facet of social condemnation, and the comparisons have been restricted to types of crimes or delinquencies in the same jurisdiction. Yet the findings suggest that the inverse relation between the objective certainty of imprisonment and crime rates *among states* (e.g., Logan, 1972) may reflect differences among states as regards the social condemnation of crimes. That is so because the fundamental argument applies both to differences among types of acts and to differences among jurisdictions. The argument is that a criminal law is seldom violated if the type of act is socially condemned to a marked degree, and that very condemnation prompts legal officials to pursue arrests and press for convictions. Those official activities could result in a greater objective certainty of punishment than would otherwise be the case (i.e., if the social condemnation of the type of crime were not intense), and the greater objective certainty may be perceived by the public, or they may persist in perceiving punishment in terms of "what ought to be." In either case, the combination of a low crime rate (official or unofficial) and high objective or perceived certainty of legal punishment would reflect the social (extralegal) evaluations of particular types of crimes, *not deterrence*. That possibility is all the more

important since there is no basis to assume that the social condemnation of particular types of crime (e.g., homicide) is even approximately constant from one state to the next.

All past research on the deterrence question at the aggregate level (comparisons of jurisdictions in particular) failed to control for social evaluations of criminal acts; at most, it has been recognized only conjecturally (see, e.g., Gibbs, 1968). The present findings, though limited to the perceived seriousness of types of acts, represent something more than conjecture. They suggest that research on the question of general deterrence is grossly incomplete unless it incorporates perceptual variables *and* controls for the social evaluation of crimes or delinquencies.

STATUS, INEQUALITY AND INNOVATION: THE GREEN REVOLUTION IN ANDRA PRADESH, INDIA *

JOHN W. GARTRELL
University of Alberta

American Sociological Review 1977, Vol. 42 (April):318-337

The manner in which status influences the trial of innovations in agriculture has important implications for agrarian development policy. Analysis of data from samples of cultivators in 84 agrarian communities in Andhra Pradesh, India, found little support for Cancian's theory that rank inhibits risk-taking, even under conditions specified as necessary for such effects. Analysis of variance results suggested that increases in status among the poor might result in as much or more of the innovation expected to increase food production as would the present concentration of new opportunities among the rich. While these results appeared to be fairly consistent across different kinds of communities, innovation increased with increased inequality in the distribution of wealth (controlling for the effects of individual status). However, knowledge in inequality slightly inhibited innovation, apparently because relatively simple information about modern farming practices was widely diffused.

Explanations of individual adoption of new ideas and behaviors in the sociological and social psychological literature have included the effects of individual attitudes and motivation, individual resources (i.e., different dimensions of status) and various contextual or community level variables. Different research traditions have emphasized different combinations of these variables. On the one hand, more psychologically oriented researchers (e.g., Triandis, 1971) have seen the trial of innovations as a function of the congruence between cognitive and affective components of attitudes, perceptions regarding the worth of the innovation and certain personality characteristics (aspirations, need achievement, self-direction, and so on). This line of reasoning has stressed the motivation necessary to behavioral change. The successful introduction of new technology is seen as crucially dependent on special personal characteristics, net of the effects of indi-

vidual social position and of social context.¹

On the other hand, the observation that greater individual resources provide the opportunities necessary to risking the adoption of new ideas and behaviors has been one of the most widely reported findings in the sociological literature.² Here,

¹ Despite pleas for attention to macrostructural variables (Summers et al., 1970), relatively few investigators have dealt with the effects of social context, particularly the community (Rogers and Shoemaker, 1971). Even where system level variables have been included in the study of innovation, design and analysis often have left much to be desired. In the recent literature on innovation in India, Saxena (1971) compared system and individual effects, but ignored aggregation effects, only looked at correlations; and one of his two samples (India) consisted of only eight communities. Sandu and Allen (1974) included both community and individual level variables in a study of Punjabi cultivators, but their sampling design included only one individual in over one-third of the villages sampled. One of the largest studies of modernization yet reported (Inkeles and Smith, 1974) concluded that variables such as education, factory experience and urbanism had the same effects on individual modernism in a wide variety of cultures. In fact, Inkeles (1969:225) concluded that macrostructural variables, despite their attractiveness to theorists, had yet to "earn their place" empirically in the study of modernization.

² Rogers and Shoemaker (1971) provide a total of 869 citations dealing with the association between innovation and education, social status, and operation size, 27% of which failed to confirm a positive association. Given the tendency for nonsignificant

Analysis and writing was supported by Canada Council Grant S75-0569. I would like to thank Jim Converse, David Gartrell, Frederick Fliegel, Bradley Hertel and the anonymous reviewers of the article for their helpful comments on earlier drafts.

the common argument has been that personality orientations intervene between individual social position and innovation (Kohn, 1969; Rogers, 1969; Inkeles and Smith, 1974; Rogers and Shoemaker, 1971). While retaining this focus on the effects of social position, other researchers (Homans, 1961; Cancian, 1967; 1972; Becker, 1970; Prattis, 1973) have placed less emphasis on individual personality traits as the intervening factor between status and innovation. Instead, these authors have cast their explanations of innovative behavior in terms of individual risk-taking. They argue that status affects the utilities associated with events in a payoff matrix, and that individuals act to maximize the expected value of their outcomes. Different arguments have been proposed for the relationship between status and perceived utility with the attendant prediction of different functional forms of the relationship between status and innovation. Homans (1961:336-58) argued that lower status persons have little to lose by innovating, and those of high status can afford to innovate and are expected to lead. However, persons of middle level status innovate less because they have been rewarded for conformity in the past. Cancian (1967; 1972) has argued that those of upper-middle status will be more conservative in terms of innovation than those of lower-middle status, but that both of these ranks will innovate more than lower status persons and less than higher status persons. This line of reasoning, which suggests a cubic relationship between status and innovation, will be considered in more detail below.

Finally, several authors (Becker, 1970; Flinn, 1970; Marsh and Coleman, 1956; Van der Ban, 1960; Prattis, 1973) have added the notion that community norms and values influence the perceived utilities of innovation. If an innovation is not normatively accepted, persons not subject to normative influence (for example, low status marginals) will innovate first. If the innovation is positively valued by the community, leaders and individuals

located in cooperative organizations designed to spread risks will innovate first.³ This argument parallels that of Homans (1961) in implying a U-shaped relationship between status and innovation. However, little attempt has been made to determine the effects of the level and distribution of community resources on innovation or on the relationship between individual social position and innovation.

Accordingly, in an examination of agricultural innovation in rural communities in Andhra Pradesh, India, the present analysis seeks to answer the following questions: (1) is the functional form of the relationship between status and innovation linear for different dimensions of status; (2) what effects do various statuses have on innovation net of other individual statuses; (3) what are the main effects on agricultural innovation of variation in community opportunity structures (the level of wealth and degree of inequality); (4) are the relationships between status and innovation the same in communities which differ in level of wealth and degree of inequality; (5) what are the policy implications of these findings for government programs aimed at agrarian change?

Given the tremendous investment in new agrarian technologies represented by efforts to introduce the Green Revolution in less developed nations, these concerns have direct policy relevance. If the effects of status on innovation are indeed linear, then equally great gains in innovation could be made by increasing the status of the poor as by directing new resources to the rich. Such a policy would result in greater equality as well. However, if the status-innovation relationship is exponential or U-shaped, then there may be advantages (besides political ones) in a policy that allows the increased concentration of resources in the hands of the rich, even if such a policy exacerbates inequality.

If innovation proved to be exponentially greater in wealthier communities,

results not to find their way into the literature, the number and proportion of such "failures to confirm" probably is underestimated by such a count.

³ This phenomenon also has been seen in the tendency of group situations to produce riskier decisions than individuals acting on their own—the "risky shift" phenomena noted in experimental psychology.

this might help to vindicate government policy directed at introducing new technology where complementary factors of production already exist. If a more equal distribution of wealth and knowledge provided a situation where innovation was higher, then efforts at redistribution might have important direct effects on innovation. If increases in innovation from increases in resources were greater in communities with lower inequality or greater wealth, then new inputs might yield higher returns in such situations.

A Modified Curvilinear Hypothesis

In an examination of status and innovation in agrarian settings, Cancian (1967; 1972) actually began from the hypothesis that, if certain conditions were met, economic risk-taking and innovation would be negatively correlated. "The better your financial position, the more you have to lose and the less you have to gain from taking chances; therefore, insofar as adopting an innovation is risky, the richer you are, the less likely you are to adopt" (Cancian, 1967:912). The higher the social status, the more likely a random change would result in downward rather than upward movement in a stratification hierarchy. However, these "inhibiting" effects of status on innovation would hold only where: (1) all risks were perfectly divisible; (2) knowledge was spread equally over all ranks; (3) the risks necessary to maintain any position in the stratification system were equal; (4) no individual could suffer total loss on a single risk; (5) nobody had so many resources that he was completely protected from loss of rank. Cancian argued that it has been precisely the common lack of such conditions which has resulted in the often observed "facilitating" effect of status on innovation, and it is the specification of these system conditions which makes his argument all the more interesting. Modifying Homans (1961), Cancian (1967:915-6) argued that the inhibiting and facilitating effects of resources on innovation would be manifest as a middle-class conservatism. Those of high status could afford to take "flyers" (lack of condition 5) and are therefore highly innovative, while those of

very low status might actually suffer total economic extinction (lack of condition 4) and are therefore very conservative. Or, perhaps, high status individuals must take calculated risks to maintain leadership (lack of condition 3). The lower-middle class were innovative because they had not been highly rewarded for conformity, while the upper-middle class found the costs of nonconformity to be higher. Despite a positive overall trend, increases in innovation due to increases in status would be lower (or even negative) over the middle part of the resource dimension.

This hypothesis also can be supported by rationales expressed in terms of differences in the opportunities available to those at the lower-middle and upper-middle ranks. The lower-middle status peasant cultivator already produces something beyond subsistence based primarily on his own family's labor. He may be able to take advantage of new technology because he can provide the additional labor requirements using his family. Because upper-middle status peasants utilize their families' labor more fully, they may have to hire labor in order to meet the increased labor demands of new seeds, fertilizers and pesticides. Even if they attempted to mechanize in order to reduce labor requirements, they still would be vulnerable to the influence of the upper strata, who often control hired labor and access to equipment and loans. The relatively well-to-do peasant cultivator may decide not to adopt an innovation because he cannot easily obtain necessary complementary production factors without increasing his vulnerability *vis-à-vis* local elites. Even where this is not a factor, he must risk a change in the source of his labor inputs as well as adopting the new technology (violating condition 3). This reasoning would suggest that the relationship between status and innovation would best be described by an exponential curve or perhaps by Cancian's third degree polynomial.

Following Cancian's work, other authors have noted middle-class conservatism effects (Fliegel et al., 1968; Kivlin and Fliegel, 1968; Bluhm and Fliegel, 1973) or have cited Cancian's demonstration of upper-middle class conservatism

(Stanfield and Whiting, 1972). On the other hand, several replications of Cancian's research (Converse and Hickey, 1975; Gartrell et al., 1973; Morrison et al., 1976) have failed to find evidence to support the presence of inhibiting effects of status on innovation. However, none of these investigations has fully addressed the conditions specified in Cancian's theory.

Research Design

This report begins with a replication of Cancian's hypothesis that those of lower-middle rank will innovate more than those of upper-middle rank, which Cancian (1972:141) claims is at the heart of his theory. It then examines the system conditions specified as necessary to the operation of the inhibiting effects of resources on innovation. Finally, it will reformulate the hypotheses within a regression analysis framework paying particular attention to: (1) the possibility of non-linear effects and (2) the effects of system conditions (here, community characteristics) on innovation.

The setting chosen for the present investigation was agrarian India, and the innovations studied were principally those involved in the Green Revolution—the combination of new seeds, chemical fertilizers, pesticides and improved tools and techniques that was supposed to render India self-sufficient in food grain production. The development efforts directed toward these innovations involved voluntaristic programs relying on persuasion, cooperation and self-help. The incentives and facilities provided often have been distributed through existing stratification systems, and inputs have been concentrated where complementary factors of production, particularly an assured water supply, already existed (Frankel, 1969; 1971). The usual reasoning that this process leads to greater inequality (Gotsch, 1972) needs to be reexamined if Cancian's hypothesis as to the inhibiting effects of status on innovation proves correct. If innovation leads to greater wealth and lower-middle peasants innovate more than the upper-middle ones, then inequality would diminish.

Sampling

The data were collected in a 1970 survey of 84 rural agrarian communities in Andhra Pradesh, India. The state of Andhra Pradesh (40 million people in an area of 106,000 square miles) is located in southcentral India. It includes both extensive areas of dry cultivation on the inland Deccan plateau (Telangana region) and relatively well-developed and densely populated rice-growing areas centered on irrigation from the Godavari, Krishna and Penna river systems along the Bay of Bengal (the Andhra region). Andhra Pradesh thus provided the wide variation in levels of development necessary to the examination of the effects of community characteristics on innovation.

Interviews with 336 knowledgeable informants based on their records and with 84 representative samples of heads-of-household (2,040 in all) were used to generate estimates of community characteristics. Fourteen villages with populations between 200 and 5,000 in 1961 were selected from census lists for each of six districts in Andhra Pradesh. The sample of villages was proportionate within high and low irrigation areas (based on the 1964–1967 average gross irrigated area divided by gross cultivated area) and the districts chosen were those ranked first, fourth and ninth in each of two regions (Telangana and Andhra) on a six-year average (1961–1967) of gross farm income per cultivating household. Since richer districts in Andhra Pradesh have fewer villages, such a sampling design over-represented relatively well-developed villages in order to expand the variance in developmental conditions within the sample.

Within the 84 villages, heads-of-household were selected in proportionate random quota samples within three strata: cultivators, agricultural laborers and others. Sampling fractions decreased as village size increased with samples ranging from 15 out of 40 households to 60 out of 863 households. While the representation of cultivators (the focus of this analysis) was proportionate within each village, the over-representation of richer villages probably insured the over-representation

of richer villagers. This may well be desirable in a situation where the distribution of resources generally is highly positively skewed, since it should yield more accurate estimates of the upper portions of the resource continuum. However, caution should be exercised in generalizing results, even to the state of Andhra Pradesh.

Replication

As we have seen above, Cancian (1967; 1972) hypothesized that those of low-middle status would innovate as much or more than those of high-middle status. In his analysis, status was conceptualized as wealth and measured in different data sets by volume of inputs, size of operation and income (Cancian, 1967:912). Cutting points in Cancian's four-rank scheme were chosen to give equal proportions at each rank (quartiles), and high risk takers were operationally defined as the top quartile of innovators. In the present analysis, the total sample ($n=2,040$) was used in estimating community characteristics, but only the heads-of-household who reported gross farm income from cultivation in 1969-1970 were included in analysing variation in trial of innovations. High risk-taking was operationally defined as the reported trial of ten or more (to a maximum of 32) innovations.⁴ Wealth was operationally defined as the sum of Rs., livestock, tools, land and agricultural buildings owned by the household.

Recognizing that status systems are multidimensional, I included: (1) a measure of jati rank as an indicator of ritual status;⁵ (2) an index of level of living con-

structed by summing the number of modern housing characteristics, luxury goods and manufactured household possessions; (3) Rs. spent by the household on jajmani services in the year before the survey as an indicator of "traditional" consumption levels;⁶ (4) the average number of years of schooling received by adult males (married or 21 years or older) as an indicator of educational resources in the household. Cutting points (Appendix A) defining the four rank levels were not chosen to produce quartiles. Rather, they were defined *a priori* to provide what appeared to be reasonable divisions for the sample as a whole (including noncultivators). Since cultivators are generally the most wealthy villagers and since resource distributions are usually positively skewed, such divisions are more consistent with the structure of village stratification systems than are the rectangular distributions implied in ranks of equal proportions (Morrison et al., 1976).

Table 1 reports the percentage of cultivators at each rank who are high innovators. These results consistently support the hypothesis that individuals of low-middle rank will risk less than those

obtain a common caste ranking for several villages are problematic. Here the jati identification of heads-of-household was obtained in the interview and a post hoc scale for ritual rank was constructed. This process began from the ranking found by Lakshman (1973) through the examination of patterns of interdining, etc. and, with the help of several anthropologists and the project's interviewers, we fitted in the other jatis. The detailed scale ranged from 99 for the highest Brahmins to 10 for the lowest "untouchable." The division used in Tables 1 and 2 (see Appendix A) includes all those with less than Sudra status in the lowest rank, all the Sudras except the highest in the next level, and all the twice-born jatis (Vaisyas, Kshatriyas and Brahmins) in the top level.

⁶ The jajmani system of relationships within Indian villages principally involves the exchange of food for goods and services, although about one-half of the transactions are now in cash. The services involved include those rendered by village artisans such as barbers, carpenters, blacksmiths, potters, weavers, priests and washermen. Links are between families rather than the jatis (castes) concerned. This system of relationships involves much more than the simple economic exchange of food for goods and services, since it includes ceremonial obligations and general obligations of mutual support between the families involved. Factional conflict usually involves the mobilization of jajmani associates.

⁴ Cancian selected the highest (or earliest) quartile of innovators because the first to try something or those who try the largest number of things presumably run the most risks. In the scale used here, scores between 10 and 32 represent the top 21.9% of the distribution. The innovation index was a count of the reported number of items of new technology tried (largely the "Green Revolution" technology of new seeds, fertilizers, pesticides, etc.). Respondents first were asked open-ended questions as to whether they knew anything about various types of new technology (for example HYV seeds) and, if they said "yes," they were then asked to specifically name those they knew about. Of those they correctly identified, the ones they said they had tried were included in the index of trial of innovations.

⁵ As Morrison et al. (1976) point out, attempts to

Table 1. Replication of Cancian's Hypothesis of (Upper) Middle-Class Conservatism

Resource Indicators	Resource Levels*							
	Low		Low Middle		High Middle		High	
	%	N	%	N	%	N	%	N
1. Jati Ritual Rank	4.1	319	12.6	269	32.6	641	37.6	85
2. Adult Male Education Years	9.6	697	14.6	158	39.4	358	55.3	103
3. Rs. Jajmani Services	2.4	207	14.1	681	35.5	335	73.1	93
4. Rs. Capital	4.4	68	4.7	450	18.6	420	49.2	378
5. Level of Living	5.2	232	10.4	531	22.2	302	61.4	251

* % = percentage of those at each resource level who were high innovators.
 N = number of observations at each resource level.

of high-middle rank. There is no evidence to support either Cancian's inhibiting effects of rank or the notion of middle-class conservatism. The relationship between resources and trial of innovations appears to be both positive and monotonic for each of the five different kinds of resources.

Extension: Controlling for the Structure of Stratification Systems

In setting conditions necessary to the operation of the inhibiting effects of resources on innovation, Cancian implied that the relationship would vary across social stratification systems. On examining the divisibility condition, it appeared that most of the elements of the Green Revolution technology aimed at rice (high-yielding variety seeds, chemical fertilizers, pesticides, etc.) were applicable to any amount of land at roughly the same cost per acre (high divisibility). They were certainly far more highly divisible than are the technologies involved in mechanization (tractors) or irrigation (tube wells). Second, Cancian made the inhibiting effects of status conditional on the equal distribution of knowledge across ranks. In this sample, knowledge inequality was measured as the Gini coefficient for the distribution of knowledge about modern agricultural technology across the household sampled in each village,⁷ and could

therefore be statistically controlled. According to Cancian's theory, the inhibiting effects of status should be more evident under conditions of low inequality in the distribution of knowledge.

In addressing Cancian's third condition, that the risks necessary to maintain any position must be equal, it seemed reasonable to expect that risks would be more equal where inequality in the distribution of wealth and knowledge were low. Inequality in the distribution of wealth was operationally defined as the Gini coefficient for the distribution of farm capital (the sum of Rs., land, livestock, machinery and farm buildings) across village household. Presumably, the inhibiting effects of resources on innovation would be stronger where there was lower inequality.

The fourth condition, that no individual be liable to suffer total loss on a single risk, is not usually satisfied in poor villages in underdeveloped countries. In these circumstances, a large proportion of subsistence farmers may suffer total loss of resources or fall into debt, particularly with vagaries of climate and disease (Nair, 1961). The level of wealth in the community can provide a cushion for such losses, besides making it less likely that scarcity will affect any cultivator. However, this is also dependent on the degree of inequality in the distribution of wealth, since there

⁷ The Gini coefficient of concentration was calculated by the algorithm $\sum_{i=1}^n (Y_{i-1}X_i) - (X_{i-1}Y_i)$ where X_i is the cumulative proportion of value in the i th category (Aker and Russett, 1964). However, the coefficient so calculated cannot reach unity and is limited to the value of Y_i where $i=N-1$ which is

$1-1/N$ (Ray and Singer, 1973). While the distortion introduced by this limitation can be serious for grouped data, the problem is easily solved by dividing the Gini coefficient by $1-1/N$. All coefficients used here are multiplied by 100 to express inequality as a percentage of area between the Lorenz curve and the line of equality.

still can be very poor cultivators in rich villages where wealth is very unequally distributed. Control on both these factors should allow us to see the inhibiting effects of status on risk-taking.

Finally, it is unlikely that the rich are completely protected from loss of rank (condition 5). Even with the highly skewed distribution of resources characteristic of many Indian communities, fortunes have changed. The land tenure reforms carried out in the early 1960s did succeed in reducing the absentee landlord (Zamindar, Jagirdar) to a much lower status, just as the combination of low taxation (Joshi et al., 1968; Rao, 1966) and new development inputs have given rise to a new rural elite (Rosen, 1967). The jajmani system has been changing for some time (Lewis, 1965; Wiser and Wiser, 1965) and, with ritual status, has become somewhat less important. However, high inequality remains and with it a situation where the local village elite may be relatively immune, at least in the short run. The greater the inequality in the distribution of wealth, the more protected are the elite and the more likely they are to take "flyers" because they have little to lose (violating condition 5).

As I have interpreted it, Cancian's theory predicts that the inhibiting effects

of rank are most likely to occur in relatively well-to-do communities where inequality in the distribution of wealth and knowledge is relatively low. If this is correct, controlling for these three dimensions of village stratification systems should give Cancian's predictions a better chance of gaining support. In this sense, inequality and level of wealth are "specifier" variables whose control allows specification of the direction of the relationship between status and innovation (Davis, 1971).

Table 2 examines the relationship between different kinds of status and trial of innovation controlling for each of the community characteristics in turn. Cultivators were divided into those who lived in villages with low and high levels of wealth and inequality with cutting points set at the means. Cancian predicted that those of lower-middle rank would innovate more than those of high-middle rank, particularly under low inequality or high resource conditions. Comparisons of the percentage of high innovators at each of these ranks uniformly failed to support this hypothesis for any of the five types of status under any of the three conditions. Even the differences between the percentages were not systematically lower in low inequality or high resource com-

Table 2. Percentage of High Innovators within Resource Ranks Controlling for Community Characteristics One at a Time

munities. Evidence for either middle-class conservatism or the inhibiting effects of status was conspicuous by its absence.

Cancian's theory might be interpreted to imply that the lack of any of his five conditions was sufficient to allow facilitating effects of rank to predominate over inhibiting effects. Each of the conditions specified would then be necessary but not sufficient for a negative relationship between resources and innovation. Only when all five conditions were met would lower-middle ranks be expected to innovate more than upper-middle ranks. This hypothesis represents what might be labeled a "weak" test of the theory, since it involves only the two middle ranks—a hypothesis which Cancian expected to hold even when these "favorable" conditions were not present.

Table 3 reports the percentage of high innovators by rank for the subsample of cultivators living in relatively wealthy communities where there was also low inequality in the distribution of both wealth and knowledge. These cultivators presumably resided in villages where the structure of the stratification system was most likely to produce inhibiting effects of status. The results in Table 3, however, provided no support for this contention. The relationship between resources and innovation was positive and monotonic with only minor exceptions. Furthermore, none of the exceptions to monotonicity involved differences between low-middle and high-middle ranks. Those with high jati ritual status had a lower percentage of

high innovators than did cultivators of high-middle ritual status. The high ritual status rank included the three twice-born varnas⁸ whose traditional occupational pursuits were not farming, while those of high-middle status (the Sudra jatis) were traditionally cultivators. In fact, religious norms traditionally proscribed active participation in cultivation by Brahmins (the highest varna). More importantly, Sudra jatis in Andhra Pradesh (60.3% of this subsample) are often numerically, politically and monetarily the dominant caste in the village—a position that yields distinct advantages in access to government development programs.

While these tabular results provide a fairly unambiguous replication and extension of Cancian's theories, they do not

⁸ Varna (literally "color") refers to the four broad classes in Indian society (Brahmins, Kshatryas, Vaisyas and Sudras) that crystallized during the Rg Veda period (roughly 1500 B.C. to 900 B.C.) and survive to the present day. The term "caste" (not to be confused with Varna) first was applied by the Portuguese to the many separate groups within the Hindu community (tribes, clans or families). Castes (a system of groups within the four Varnas) are normally endogamous, commensal and roughly craft exclusive (except for agriculture). They are therefore composed of people related by blood or marriage and are usually restricted to a particular linguistic region. Jati is a term from the Indian literature meaning caste. The twice-born castes refer generally to those of the three highest Varnas who were born again (Upanayana) when they were invested with the sacred thread initiating them into the Aryan community. Sudras and lower castes were never allowed to undergo this ceremony, nor were they allowed to hear or learn the most sacred scriptures (Basham, 1959).

provide sufficient information to examine the policy-relevant concerns outlined initially. We cannot assess whether or not there would be greater returns of innovation to increases in resources among the rich. Neither can we fully evaluate the independent impact of different dimensions of status and community characteristics on innovation. We have established only that, at first glance, higher status individuals generally appeared to be more inclined to take risks by adopting agricultural innovations regardless of the characteristics of the village stratification system in which they lived.

Regression Analysis: The Functional Form of the Status-Innovation Relationship

As we might expect from the results observed above, the zero-order correlations between the five status dimensions and innovation were all positive (Appendix B). Cancian's (1967; 1972) hypothesis would suggest that where y = innovation and x = resources, a polynomial in the form

$$y = \alpha + \beta_1 x_1 - \beta_2 x_1^2 + \beta_3 x_1^3 + u \quad (1)$$

would yield a more accurate description than would simple linear regression. If such were the case, a program aimed at redistributing land from the rich to the poor (making all holdings middle-sized) might have negative consequences for innovation. Also, a comparison of estimated slopes over different portions of the resource continuum might give some clues to where new inputs might be most profitably invested in order to maximize innovation.

Several modifications to these predictions might also be anticipated. Since the poorest villagers (agricultural laborers) were omitted from the analysis, the observation of a second degree polynomial (quadratic) in the form

$$y = \alpha - \beta_1 x_1 + \beta_2 x_1^2 + u \quad (2)$$

might satisfy Cancian's arguments. This parallels his comments on the studies cited by Homans (1961:336-58) in support of a U-shaped curve. This hypothesis would imply that increases in resources

for cultivators with low status could be counterproductive, while increases in status for the well-to-do would result in increased innovation. One might also extend this reasoning to predict an exponential curve in the form

$$y = e^{\alpha + \beta_1 x_1 + u} \quad (3)$$

if the lowest statuses were omitted from what was, in fact, a U-shaped quadratic relationship (2). In this case, while returns to innovation from increase in status generally would be positive, returns to increases in resources would be greater the higher the level of the status.

Table 4 reports one-way analysis of variance results relating each dimension of status to innovation. While the large sample size tended to yield significant differences between n^2 and r^2 (a test for non-linearity) in several instances, plots of the curves indicated that innovation appeared to be a roughly linear function of both male adult education and level of living. Increases in education or level of living among relatively disadvantaged cultivators would appear to result in approximately the same increase in innovation as would increases in these resources for those who have relatively high status.

On the other hand, the relationship of jajmani services received and wealth with innovation appeared to be best described by the logarithmic function

$$y = \alpha + \beta_1 \log x_1 + u. \quad (4)$$

Log Rs. jajmani services and log Rs. wealth were significantly more highly correlated with trial of innovation than were the untransformed versions of these variables (Appendix B).⁹ As the level of household wealth and jajmani services received increased, the rate of increase in innovation decreased. Increases in these statuses (the only ones measured in monetary terms) would appear to produce more innovation among those of low status than among those of high status. Presumably, redistribution of such resources aimed at

⁹ Comparisons of these correlations with those for the untransformed versions of these variables yielded $t=2.58$ ($P<.002$) for wealth and $t=8.97$ ($P<.001$) for jajmani services received. Other than in these two instances, simple linearizing transformations did not significantly increase the amount of variance shared between status and innovation.

reducing inequality also would increase innovation.

The relationship between jati ritual rank and innovation was somewhat more complicated. There was little change in innovation over the first three levels of jati ritual rank. These levels represented relatively poor cultivators who were at the very bottom or below the four-rank Hindu varna scheme. They resort, at times, to hiring themselves out as agricultural laborers or they may pursue other low status "artisan" occupations (washerman, potter, weaver). Over the next two levels (middle and high Sudras), there were increases in innovation. These Kapu jatis traditionally have been cultivators and are more likely to pursue cultivation full-time. More important, as mentioned above, they are often numerically, monetarily and politically the dominant caste group in Andhra and Telangana villages (Eliott, 1970). For the same reasons, it is not surprising that the Pancha Brahma castes¹⁰ and the Vaisya jatis (traditionally merchants) showed lower levels of innovation. Their economic fortunes often have been much less than those of the Sudras and many may still pursue their "traditional" occupations in addition to growing crops. They formed only a small proportion (3.5%) of the cultivators in the sample, most of whom were either Sudras or Harijans. Finally, the Kshatriyas and Brahmins (3% of the sample) had the highest innovation scores. Brahmins who cultivated land did not seem to be particularly constrained by religious norms proscribing active participation in cultivation.

If the Pancha Brahma and Vaisya jatis were considered to be the upper-middle rank, then innovation for this rank was lower than that for the next lowest group, the upper level Sudras. While this would appear to be exactly the result predicted by Cancian's theory, ritual caste status is

¹⁰ The ritual rank assigned to these jatis (traditionally carpenters, blacksmiths, sculptors and goldsmiths) is questionable. Dube (1967) placed them below the upper Sudra castes in his study of Sharmirpet (a village in Telangana close to Hyderabad), but noted that even the untouchable Madiga viewed the taking of food or drink from these castes as "bad luck." On the other hand, Pancha Brahma castes will not accept food or drink from even the Brahmins.

practically immutable, since one is born into a jati. Therefore, it cannot be risked, and Cancian's fifth condition would be violated. As a consequence, there should be only positive effects of ritual rank on innovation (Morrison et al., 1976). In fact, while the relationship was positive, it was hardly a simple linear function. Even the nonlinear eta-squared for jati ritual rank and innovation was lower than the zero-order linear correlation for the other status dimensions (Table 4). To summarize, the relationship between jati ritual status and innovation was both complex and relatively weak. Although it was difficult to measure accurately, ritual status per se appeared to have had far less influence on innovation than many sociological and anthropological writings on India would have led us to believe.

Increases in innovation appeared to be a linear function of both education and level of living. Equally large gains in innovation could be made by distributing new resources of these kinds to the poor rather than to the rich. Since independence, emphasis on providing free universal elementary education to villagers may well pay off in both higher innovation and greater equality. This would occur as cohorts which have had the advantages of this basic education become cultivator heads-of-households.¹¹

Finally, innovation was a linear function of the logarithm of jajmani services received and total Rs. agricultural capital (wealth). The higher a head-of-household's status on these resource di-

mensions, the lower the increase in innovation per unit increase in status. The effects of caste on innovation appeared to be manifested more through services rendered in the village jajmani system than through ritual status per se. However, increased participation in this system of exchange had increasingly lower payoffs in innovation the higher the level of services received.

Besides the obvious effects on inequality, redistribution of land (the principal component of farm capital) might result in greater innovation. However, government programs appear to have been far less successful in redistributing wealth than they have been in increasing educational equality. While there has been an obvious commitment to greater equality in government rhetoric, land reform has not radically altered the distribution of land (Singh and Misra, 1964:148; Sharma, 1967: 231; Indian Institute of Public Opinion, 1968:58). Settlements with Zamindars were perhaps too generous, as were land ceilings which were applied to individuals instead of families or even households. Nonretroactive legislation was conveniently delayed to allow circumvention of the law. Tenancy legislation often resulted in many tenants losing their rights when owners resumed cultivation of their lands using managers and hired labor (Varghese, 1970; Sonachalam, 1970; Government of India, 1966). Taxation based on land remained regressive, while inflation drastically reduced its impact (Rao, 1966; Joshi et al., 1968). In short, agricultural wealth was not effectively redistributed by reform legislation. In addition, the effects of community development and agricultural extension programs were directed primarily at wealthier villages in wealthier regions and largely at relatively well-to-do cultivators (Frankel, 1972; Parthasarathy, 1974; Tripathy, 1974; Gotsch, 1972; Myrdal, 1968). If the present results for cultivators in 84 villages in Andhra Pradesh are any indication, agrarian development does not appear to have proceeded in a manner most conducive to the innovation expected to yield higher food production.

¹¹ Each of the 84 randomly selected villages had an elementary school. Inequality in the distribution of education for adult males was still high ($\bar{X}=73.41$) and levels of education were still low ($\bar{X}=2.27$ years). However, there was some evidence that new educational inputs have been going to the disadvantaged, since village educational levels and inequality in the distribution of education were negatively correlated ($r=-.63$). Differences between villages in education levels may have been partially a function of the timing of these new inputs. Communities which received schools first would be more likely to show the effects in adult cohorts. However, education beyond the primary grades remains a considerable expense (travel, lodging, books, etc.), since higher level schools are usually located in towns.

Status Dimensions as Predictors of Innovation

Each of the five dimensions of status had fairly substantial effects on innovation (zero-order correlations ranging from .328 to .589). However, when innovation was regressed on all five status variables simultaneously, the influence of jati ritual rank was not significant. Controlling for the other four status variables (Table 5), its fifth-order partial correlation with innovation was virtually zero ($r = -.006$) and it was therefore omitted from the equation reported in Table 5. Its effects appeared to be indirect through other aspects of status and only in this sense was it a barrier to innovation and change. These results paralleled those of Roy et al. (1968) and provided further support for the contention that caste status is not the overwhelming determinant of behavior in village India.

The multiple regression results also showed log farm capital to have only modest effects on innovation net of other status dimensions ($\beta = .145$). While differences between the betas were based on only small differences between the zero-order correlations (Appendix B), one possible explanation for the relatively weak impact of wealth on innovation may lie in the partially commercialized nature of agricultural production in Andhra Pradesh.¹² Also, the relative importance

of capital investment may have been lower, since labor-intensive technologies were dominant particularly for the Green Revolution technology organized around high-yield varieties of rice. However, a number of conditions have prevented the greater utilization of labor: climate, low nutritional and health standards, poor wages and institutionalized conditions which insure the poverty of laborers' economic and social position, little training or development of laborers' skills, and the relative lack of labor mobility along with the imperfection of markets that results. As Myrdal (1968) argued, investment in new technology cannot be utilized effectively until such conditions are altered to allow the improvements in labor efficiency necessary to increased production.

The effects of level of living may have reflected underlying dimensions of modernism—the consumption of modern goods and the trial of modern agricultural technology. In fact, Rogers (1969) has treated similar indices of level of living precisely in this manner. However, increases in both traditional and modern forms of consumption appeared to have resulted in increased innovation net of other dimensions of status. Maintenance of traditional jajmani service relationships within the village appeared to be important in this respect, and it was this aspect of the caste system that was important

¹² For example, an average of 47.58% of the crops in a village were sold ($S=16.41$), while the average percentage of jajmani services paid for in cash was 40.76 ($S=24.31$). While many cultivators still do not think in monetary terms and keep no records, there

appears to have been a rather slow shift from exchange in kind towards exchange in cash (compare with Iyengar, 1931). Because of the substantial inflation since World War II, this change has been resisted by those providing the service or labor.

Table 5. Status and Innovation: Multiple Regression Results

Variable	B	Std. Error B	F	Standardized Beta	Std. Error Beta

S _e =3.21	Residual	1,309	13,453.83	10.28	

rather than ritual status per se. Certainly, the positive sign of the coefficients for both consumption variables failed to indicate any support for arguments suggesting a trade-off between consumption and innovation due to scarce resources.

The positive effects of education ($\beta = .177$) suggested that increased innovation from recent increased inputs of primary education will operate independently of other status dimensions. On the other hand, there is disturbing evidence that the poor in rural India have not enjoyed gains in their level of living over the 1960s and can look forward to more of the same in the 1970s (Government of India, 1968; Dandekar and Rath, 1971). If gains in the level of living continue to go to those who already enjoy a relatively high standard of living, increased innovation may be gained only at the cost of greater inequality.

In summary, the effects on innovation of traditional and modern consumption, education and wealth were all positive. Together these four dimensions of status accounted for 45.3% of the variance in trial of innovations. The effects of caste ritual status on innovation appeared to be indirect through these dimensions of status. While the trial of new technology was linked more closely to consumption than to capital resources, one should not emphasize these differences in partial regression coefficients too much, since they were based on rather small differences in zero-order correlations (Gordon, 1968). More importantly, wealth is obviously necessary to the purchase of jajmani services, housing improvements, modern consumer goods, education beyond the primary level, and the new Green Revolution technologies themselves. In this sense, the effects of wealth on trial of innovation may be partially indirect through consumption and education.

The same three dimensions of community stratification systems introduced above (Cancian's conditions) were considered as predictors of innovation: (1) the degree of inequality in the distribution of farm capital across household in the community (wealth inequality); (2) the degree of inequality in the distribution of knowledge about modern agricultural

technology (knowledge inequality); (3) the average household farm capital (level of wealth). While there was little well-formulated theory to "fall back on" in attempting to link these community characteristics to innovation, I speculated that inequality would impede the diffusion of innovation and that higher levels of wealth would enhance it. The reasoning behind this prediction of negative effects for inequality rested on the notion that people of similar social status were more likely to share information and to provide the social support necessary to the reduction of risks. Indeed, the latter appears to have been particularly relevant for a sample of Pennsylvania farmers (Fliegel et al., 1968). Stanfield and Whiting (1972:414) noted that Brazilian farmers in communities with less land-ownership concentration were somewhat more innovative, although they concluded that "the degree of land-ownership concentration produced disappointingly few direct effects."

On the average, cultivators faced stratification systems with relatively few resources present where knowledge was relatively widely diffused, but wealth was highly concentrated. Both wealth and knowledge inequality had significant independent effects on trial of innovation (Table 6), but the level of community wealth did not.¹³ While it was positively correlated with innovation ($r = .236$, Appendix B), it had little effect independent of individual status. The small negative effects of knowledge inequality on innovation lent only weak support to arguments that knowledge inequality inhibited the diffusion of innovation. On the other hand, as opposed to results reported by Stanfield and Whiting (1972), inequality in the distribution of wealth had substantial positive direct effects on innovation. Beyond the notion that high inequality reduced risks to status, high inequality also positively covaried with the presence of the labor resources necessary to the implementation of Green Revolution innovations ($r = .66$). In addition, the positive

¹³ The partial correlation of level of wealth and innovation controlling for the variables in Table 6 was $-.003$; that for jati ritual status with the same controls was $-.001$.

Table 6. Effects of Community Characteristics and Individual Status on Trial of Innovation

R ² =.467	Reg.	6	11,484.43	1,914.07	190.92
S _e =3.166	Res.	1,307	13,103.51	10.03	

effects of wealth inequality on innovation may indicate that, where resources were scarce and many peasants operated at the margins of subsistence, concentration of resources facilitated risk-taking. However, one should not overestimate the importance of these effects. While the addition of community-level wealth and knowledge inequality to individual status dimensions as predictors of innovation resulted in a significant improvement in the accuracy of prediction, the increment in R^2 was small ($R^2 = .467$ versus $.453$).

The lack of significant effects of community wealth levels on innovation suggest that innovation may not have been enhanced through disproportionate investment in wealthier communities. This would question the efficacy of government policy directed at the introduction of new technology where complementary factors of production already existed. While knowledge inequality had only very small direct effects on innovation, they were negative. The wider diffusion of information within communities might encourage innovation slightly. Since wealth inequality had positive indirect effects on innovation, in one sense the failure of redistribution programs and the concentration of new inputs actually may have resulted in greater innovation. Note, too, that these effects, while relatively weak, were independent of individual status. In villages with high inequality, all cultivators innovated more, whatever their status.

The Interaction of Community Characteristics and Individual Social Status

Given the paucity of writings directed at the specification of the interactions in question, analysis was necessarily exploratory and the reasoning speculative. There appeared to be no evidence that the relationship between properties of community stratification systems and innovation substantially suppressed the relationship between status and innovation. When wealth and knowledge inequality were controlled, the standardized partial coefficients representing the direct effects of status on innovation remained roughly the same (compare Tables 6 and 5). Similarly, cross-tabular results (Tables 2 and 3) did not suggest interactions between status and community-level measures. While I found little evidence confirming Cancian's theories for this sample, his appears to have been one of the few analyses which explicitly considered the system conditions under which the effects of status on innovation might vary. Extrapolating somewhat from his theory, we might speculate that lower inequality and higher levels of wealth at the community level would result in increasingly negative effects of status on innovation at the individual level. The simplest way to handle such interactions within an additive regression model was to add new terms to the prediction equation composed as the

multiples of individual status and community characteristics.¹⁴

After controlling for individual statuses, knowledge, inequality and wealth inequality (Table 6), none of the 15 first-order interaction terms could be added to the model. Correlations between the interaction terms and the variables which composed them ranged from .66 to .82, with most of the coefficients around .70, and serious problems of multicollinearity resulted.

Instead of judging whether the entire set of cross-product terms added significantly to explained variance (Blalock, 1972:464), forward stepwise regression was used to see if any of the interaction terms could be included. The results (Table 7) included only one of the 15 terms—the product of wealth inequality and adult male education years. It was more highly correlated with innovation net of the two consumption status indicators than were the main

effects of wealth and education status. This interaction term also was highly correlated with each of the main effects (wealth inequality $r = .742$, education $r = .744$), and it replaced these main effects in the model (compare Tables 6 and 7). The positive standardized partial regression coefficient for the interaction term ($\beta = .207$) indicated that having high education status in a village with high wealth inequality was conducive to innovation. However, accuracy of prediction (Table 7) was not greater than that obtained with only main effects (Table 6), and the coefficients for the main effects included in Table 7 differed only slightly from those in Table 6. While one might ordinarily prefer the more parsimonious equation with five predictors (Table 7) over that with six (Table 6), the inclusion of an interaction term in the former largely obviates this reasoning. Problems of multicollinearity also render the difference between the two equations difficult to interpret.

Finally, in order to explore further the possibility of interaction effects, innovation was regressed on individual status variables for the subsample of cultivators in low-inequality, high-resource communities. These conditions attempt to represent the situation in which Cancian reasoned that the inhibiting effects of status on innovation (negative slopes) would be most likely to be manifest. While average innovation was slightly higher in these communities (compare Table 8 with Appendix B), regression results again showed little support for Can-

¹⁴ First-order interactions were computed for all five dimensions of individual status with the three community characteristics after the means of each variable was set to 100. This procedure, as well as the focus on standardized coefficients, avoids some of the problems in interpreting the effects of the interaction terms (Althausen, 1971). However, problems with multicollinearity and the kinds of issues discussed by Gordon (1968) remain. The correlation matrix containing all these first-order interaction terms and the main effects could not be inverted because of problems of singularity. However, stepwise regression effectively eliminated several interaction terms which were virtually linear combinations of other variables. Rockwell (1975) provides a discussion of problems of multicollinearity and suggests several helpful "coping" strategies.

Table 7. Multiple Regression Including First Order Interactions between Individual-Status and Community-Level Variables

Variable	B	Std. Error B	F	Standardized Beta	Std. Error Beta

cian's theory. All zero-order correlations between status and innovation were positive, as were the standardized partial slopes for the variables included in the prediction equation (Table 8). The latter coefficients also were similar to those for the total sample (Table 5). However, increases in wealth appeared to produce somewhat larger increases in innovation and level of living had nonsignificant effects net of jajmani services, education and wealth.¹⁵ This reflects the magnitude of the zero-order correlations, since the only substantial difference of interest for the subsample was in the correlation of level of living with trial of innovations ($r = .370$ for $n = 292$, $r = .589$ for $n = 1,314$). In low-inequality high-resource villages, consumption mattered much less and wealth influenced innovation somewhat more.¹⁶ Even though the correlations be-

tween these different dimensions of status were not high enough to inflate standard errors seriously, this only serves to reinforce caution in interpreting differences between the coefficients for the various status variables.

As was emphasized above, this analysis of interactions has been exploratory. While there are many additional interactions between individual status and community characteristics which could be included to continue this exploration, the results discussed above and the difficulty in interpreting higher order interactions make this line of inquiry appear to hold little promise in the absence of well-reasoned theory. There were, however, some indications of possibly significant interactions between different community characteristics. I have already noted that average inequality in the distribution of knowledge about modern agricultural practices was relatively low. More importantly, for the 84 communities there was a large negative correlation between the average level of knowledge (x_1) and in-

¹⁵ The third-order partial correlation of level of living with innovation was $-.077$, while that for jati ritual rank was $-.044$. The latter result was consistent with that found for the total sample (Table 5).

¹⁶ These differences would be magnified in comparisons between cultivators in low-inequality, high-resource villages and all other cultivators. Presumably, in the latter sub-sample, the partial slope for level of living would be even higher and that for

log wealth even lower than was the case for the total sample.

equality in its distribution (x_2 ; $r_{12} = -.74$). Once information entered the village, it was widely diffused. This relationship suppressed the correlation between wealth inequality (x_3) and knowledge inequality ($r_{23} = .41$), yielding a higher partial correlation between wealth and knowledge inequality controlling for the level of knowledge ($r_{23.1} = .55$). Widespread diffusion of information in densely settled nucleated villages appeared to reduce the otherwise high impact of wealth inequality on knowledge inequality. This diffusion effect also helped to specify the relationship between inequality in the distribution of knowledge and trial of innovations (x_4). While the zero-order correlation between knowledge inequality and innovation was small and negative ($r_{33} = -.06$), the first-order partial correlation controlling on community knowledge level was positive ($r_{33.1} = .26$). The small inhibiting effect of knowledge inequality on innovation (Table 6) appeared to have resulted, in part, from the relatively wide diffusion of knowledge within these villages. These and other results suggest that future analysis should attempt to expand the community characteristics considered.

Conclusions

The idea that social structure affects individual behavior has pervaded social science for some time. There appears to be only weak empirical confirmation for such effects in these exploratory results, since the independent effects of the structure of community stratification systems on innovation were modest, and there appeared to be few simple interactions of much consequence between system characteristics and individual status. Community effects may have been weak because government intervention, urban influence, greater mobility and the penetration of regional markets have become increasingly important determinants of the behavior of Indian villagers.¹⁷ In fact, it is

possible that systematic and random errors in measuring individual level variables may have understated their effects, a situation complicated by the likelihood that such errors are probably nonlinear. Knowledge and wealth inequality at the community level may have picked up some of the variance in innovation left unexplained by these measurement errors. On the other hand, the relationship between the distribution of statuses and inequality is certainly complex, and may itself be nonadditive, particularly since inequality systems are not easily distinguishable from their manifestations in the distribution of inequality and Gini indices are only aggregations of individual inequalities. The system of inequality most certainly has effects not captured by the few simple measures employed here, and those effects may have been concealed in individual-level measures of status.

Innovations are not necessarily risky just because they are new. Indeed, since innovations in agriculture and elsewhere are directed primarily at improving production, they often reduce risk. Contrary to the situation in the U.S.A. and Canada, it does not appear that economic production risks associated with Green Revolution innovations in South India are highly indivisible or call for complicated organization. Neither are such technologies created specifically for those with greater resources (Hightower, 1972). In this Indian sample, individual utilities apparently lead cultivators to make decisions regarding innovation that are consistently a positive function of status, even in communities which vary widely in the structure of their stratification systems.

Since these relationships were linear or linear for the log of status, innovative behavior at lower status levels might be af-

relationship between status and innovation. The standard deviation for land inequality (the major component of wealth) was 13.45 and the mean was 72.19 for the 84 communities. The average Gini coefficient for the distribution of land for 50 nations was reported as 71.7 with $S=13.9$ by Russett et al. (1967:239). The update on these figures (Taylor and Hudson, 1972:267-8) found a mean of 67.0 and a standard deviation of 15.2 ($n=54$). There appears to be almost as much variability across village communities in a single Indian state as there is across the nations of the world.

¹⁷ While the range of development levels and inequality encompassed by these 84 communities was surprisingly large, this too might have contributed to the lack of identifiable systematic differences in the

affected by the subsistence needs of the family. Furthermore, the magnitude of proportionate differences in the investment necessary to innovation may protect the rich, as may other institutions. Even at the relatively low levels of development represented in this sample, there was little systematic evidence to suggest that scarcity of resources dictated a trade-off between spending for consumption and the investment necessary for the trial of modern farm technology. Higher levels of wealth appear to have allowed both.

Future research also must consider the degree of uncertainty involved in innovation, since there is usually wide variation by social status in the degree to which risks are clearly calculable. While aware-

ness of agricultural innovations may be widely diffused, everything from experiential grounding through prior innovation to the distribution of credit renders these risks far less certain for poorer cultivators. As a result, awareness of innovation is probably translated into trial at different rates for different levels of resources. If future research is to represent proportionate risks more directly, the utilities associated with innovations need to be considered more closely and different types of innovations need to be sampled. Furthermore, the magnitude of feedback over time between innovation, resource accumulation and status must be explored if agrarian development policy is to find a firm base in sociological research.

ARMS RACES: A TEST OF TWO MODELS*

ROBERT L. HAMBLIN, MICHAEL HOUT, JERRY L. L. MILLER, BRIAN L. PITCHER

University of Arizona

American Sociological Review 1977, Vol. 42 (April):338-354

This is an investigation of two models of arms races: Lewis F. Richardson's linear, additive, symmetric model and a curvilinear, asymmetric alternative based on the same interaction paradigm but with empirical equations from psychophysical experiments on perception as premises. Two hypotheses derived from each model are tested using data from seven arms races. In general, the data give stronger support to the curvilinear, asymmetric model which predicts the follower in the arms race will increase its armaments through time as an exponential function of the leader's armaments, and the leader will increase its armaments as a power function of the follower's efforts at the previous time period. The conclusions are based on the relative fit of the models to the seven sets of data, parsimony, reasonableness of the parameter estimates as adjudged by their signs and magnitudes, and predictions about the outcomes of the races—war or armed truce.

Lewis F. Richardson's (1939; 1960) analysis of arms races has become a classic in mathematical conflict theory and research. Although more or less ignored at first, his contributions have been popularized by Rapoport (1957; 1960), Boulding (1962) and Rashevsky (1959). Others have continued his tradition, suggesting interesting modifications (cf. Smoker, 1965; Abelson, 1963; Saaty, 1968). His work stands out, in our opinion, for its mathematical sophistication and for the concern shown for empirical evidence.

The purposes here are (1) to review Richardson's model, (2) to derive implications which may be used in its empirical evaluation, (3) to develop a modified interaction model using empirical generalizations from modern psychophysical research about perception as premises, (4) to derive the implications and (5) to evaluate the relative adequacy of the two models using data from seven arms races.

* The first author was responsible for working out the second model of arms races presented here. All authors wish to thank Paul Fife and Robert O'Malley, Professors of Mathematics, and Ronald Schoenberg, Assistant Professor of Sociology, for their suggestions for solving mathematical and computational problems encountered in this research. This research was supported by an NSF grant, SOC 75-08448.

RICHARDSON'S MODEL

Richardson (1960:14) started his exposition with a "quote" from a speech of the Defense Minister of "Jedesland":

The intentions of our country are entirely pacific. We have given ample evidence of this by the treaties which we have recently concluded with our neighbors. Yet, when we consider the state of unrest in the world at large and the menaces by which we are surrounded, we should be failing in our duty as a government if we did not take adequate steps to increase the defense of our beloved land.

Richardson suggested that a simple mathematical representation of the above rationale for increasing armaments is:

$$dy/dt=kx, \quad (1)$$

where dy is the increment in armaments by nation Y, dt is the increment in time, k is a positive constant named a defense or *insecurity* coefficient, and x represents the cumulative armaments of nation X, the menaces of which nation Y is "surrounded." A similar equation may be written for nation X:

$$dx/dt=ly, \quad (2)$$

where l is a positive insecurity coefficient and y , the accumulative armaments of nation Y.

However, this formulation may be criticized because it leaves out terms for the fatigue or expense of keeping up defenses. So Richardson (1960:15) "improved" the equations:

$$dy/dt = kx - ay, \quad (3)$$

$$dx/dt = ly - \beta x, \quad (4)$$

where α and β are fatigue coefficients and the other variables and constants are defined as before.

Richardson's (1960:16) final differential equations include g and h as constants representing Y and X 's respective ambitions or grievances toward the other:

$$dy/dt = kx - ay + g \quad (5)$$

$$dx/dt = ly - \beta x + h. \quad (6)$$

This system of equations can be conveniently expressed in matrix notation:

$$\frac{d}{dt} \begin{bmatrix} y \\ x \end{bmatrix} = \begin{bmatrix} -\alpha & k \\ l & -\beta \end{bmatrix} \begin{bmatrix} y \\ x \end{bmatrix} + \begin{bmatrix} g \\ h \end{bmatrix}, \quad (7)$$

$$\frac{d}{dt} Z = BZ + A. \quad (8)$$

In this form, it is possible to solve for cumulative armaments at time t , $Z(t)' = [y \ x]'$, as a function of cumulative armaments at time $t-1$, $Z(t-1)$, using the theory of linear nonhomogeneous differential equations (Boyce and DiPrima, 1969:317-21; Kaufman, 1976) if $\alpha\beta - kl \neq 0$:

$$Z(t) = e^B Z(t-1) + (e^B - I) B^{-1} A, \quad (9)$$

$$= B^* Z(t-1) + A^*, \quad (10)$$

where $e^B = I + B + B^2/2! + B^3/3! + \dots$.¹ The component equations are:

¹ According to Kaufman (1976), Coleman (1968:449-51) and Land (1970:271-2) erroneously state that $A^* = B^{-1}A$. Kaufman (1976) presents a solution for a more general system that includes exogenous variables. Richardson (1960:37-41) presents solutions derived from several simplifying assumptions. The solution in (9)-(10) requires none of Richardson's simplifying assumptions and is, therefore, more appropriate for the empirical analysis here. Although e^B is defined by the infinite series $I + B + B^2/2! + B^3/3! + \dots$, a formula that is computationally simpler for the 2×2 case is:

$$e^B = \frac{e^{\lambda_1}}{\lambda_1 - \lambda_2} (B - \lambda_2 I) + \frac{e^{\lambda_2}}{\lambda_2 - \lambda_1} (B - \lambda_1 I),$$

if $\lambda_1 \neq \lambda_2$ where λ_1 and λ_2 are the eigenvalues of B .

$$y(t) = b^*_{11}y(t-1) + b^*_{12}x(t-1) + a^*_1, \quad (11)$$

$$x(t) = b^*_{21}y(t-1) + b^*_{22}x(t-1) + a^*_2. \quad (12)$$

Equation (10)—or equivalently, equations (11)-(12)—can be used to estimate empirically the parameters of Richardson's model. The fit of the estimated model to the data and the pattern of the parameter estimates can then be used to compare Richardson's model with alternatives. (If $\alpha\beta - kl = 0$, then B^{-1} does not exist and A^* is ill-defined.)

AN ALTERNATIVE MODEL

One reason Richardson's model has appealed to so many is that the parameters in the differential equations are interpretable as measures of insecurity, fatigue and grievance. Also, the estimates of the parameters may be used to predict whether an arms race is stable and thus will result in armed truce or is unstable and thus will result in war (cf. Richardson, 1960:22-3; Blalock, 1969:106-9; Coleman, 1968:448-9). These may be very desirable features, but they are irrelevant if Richardson's model is mis-specified. That is, Richardson's linear, additive differential equations—particularly in their representations of the "insecurity" and "fatigue" parameters—may not correctly describe the actual interaction process. Richardson's initial verbal description seems to suggest that the insecurities are intervening variables, with the causal sequence diagrammed as follows: X 's insecurity \longrightarrow X 's armaments \longrightarrow Y 's insecurity \longrightarrow Y 's armaments \longrightarrow X 's insecurity, etc. This sequence implies that the form of the equations ought to be congruent with equations for perception, specifically those which have emerged from psychophysical experiments. In fact, Richardson (1960:14, 95-7, 105-6) considered modifying his model by incorporating Fechner's psychophysical equation. However, Fechner's logarithmic equation was then under attack, in part by Richardson himself who did several psychophysical experiments (cf. Richardson, 1928; 1929; Richardson and Ross, 1930) which anticipated the more definitive work

of S. S. Stevens (cf. Stevens, 1957; 1961; 1962; 1971; 1972; 1975).

Stevens' equation is one of the generalizations used in the modification proposed here. His experimental results imply an underlying curvilinear model where the relative change in a psychological sensation ($d\psi/\psi$) is a constant proportion (n) of the relative change in the related stimulus ($d\phi/\phi$) or:

$$d\psi/\psi = n d\phi/\phi. \quad (13)$$

Stevens' power function, the solution of this differential equation, has been shown to describe quite accurately the behavior of a wide range of perceptual attitudinal interactions (cf. Stevens, 1966; 1972; Hamblin, 1966; 1971; 1974) including the negative sensations, not unlike insecurity, that accumulate through time in "low stakes" conflict (Hamblin, Bridger, Day and Yancey, 1963).

Like Richardson's original, the model of arms races proposed below assumes a vicious cycle of interaction wherein the armament increments by each party increase the insecurity of the other, leading both to further increments in armaments and, in turn, to further increases in insecurity. However, it differs from the original model in at least four ways. (1) As mentioned, the forms of the differential equations are congruent with appropriate generalizations for psychophysical experiments. (2) The process is assumed to be asymmetric. All of the arms races indicate a leader who is always in front, evidently taking the initiative, and a follower who is always behind, evidently under duress, trying desperately to catch up (see the data in Appendix A). The duress results in a form of interaction for the follower which is different from that of the leader. (3) The leader's equation is lagged because the asymmetric interaction is assumed to occur in sequence, not simultaneously. (4) The fatigue or expenditure variable is eliminated from the equations primarily because it may not be relevant to the shape of an arms race, only to the outbreak of hostilities (when the leader's advantage is optimal) or its termination (when a sufficient deterrence or overkill capacity is achieved).

The Follower's Response Pattern

Assume that Y suddenly finds itself substantially behind X in armaments and, because of the competitive, hostile relations between the two, its decision makers are highly threatened by their relative weakness. Suppose further that under such conditions of high threat or duress, sensory adaptation occurs. Consequently, the accumulated insecurity not only mediates Y's armament effort but modifies it from round to round, not unlike the adaptation of the eye or the ear to the cumulative effects of light or noise in the recent past. Psychophysical experiments on adaptation by Ekman (1970) have yielded data described not by Stevens' power function but by an exponential equation. Assuming adaptation because of duress and, hence, the applicability of Ekman's findings, the increment in the insecurity of Y's decision makers (dI) should increase as a constant proportion (c) of their cumulative insecurity (I), times the increment (dx) in armament effort of X, as in the following differential equation:

$$dI = c I dx \text{ or } dI/I = c dx. \quad (14)$$

If the response to the cumulative insecurity follows Stevens' psychophysical equation as implied by experimental results on other sensory phenomena (see Hamblin, Clairmont and Chadwick, 1975), then the relative increase in Y's armaments (dy/y) at time t should be a constant proportion (p) of the relative increase of Y's decision maker's insecurity (dI/I) at time t , as in the following differential equation:

$$dy/y = p dI/I = p c dx = m dx \text{ or } dy/dx = m y \quad (15)$$

where $m = p c$. If (15) is integrated to solve for $y(t)$ as a function of $x(t)$ one obtains:

$$y(t) = be^{mx(t)}, \quad (16)$$

where b is partly a scaling constant and partly a grievance parameter. This is the first of two alternative hypotheses which can be empirically compared to Richardson's linear model using arms race data.

The Leader's Response Pattern

Because X started the arms race, has a superior arms stockpile and always takes

the *initiative*, the insecurity of its decision makers has to be determined by what has happened previously. Also, because X is ahead in the race, its decision makers are assumed not to act under duress and, therefore, not to experience adaptation. Therefore, they behave like subjects in Stevens' experiments, where adaptation is absent or controlled, and like actors in "low stakes" conflict (Hamblin et al., 1963). Thus, the relative increases in insecurity (dI/I) should be a constant proportion (k) of the relative increase in Y's armaments (dy/y) with some time lag:

$$dI/I = k L(dy/y) \quad (17)$$

where L is a lag operator. If, as before (equation [15]), it is assumed that the relative increase in X's armaments (dx/x) will be a constant proportion (h) of the relative increase in X's insecurity (dI/I) then

$$\begin{aligned} dx/x &= h dI/I = h k L(dy/y) \\ &= n L(dy/y). \end{aligned} \quad (18)$$

If (18) is integrated to solve for x , one obtains:

$$x = s[L(y)]^n, \quad (19)$$

where s is partly a scaling constant and partly an aggression parameter. Because the data are in discrete years, we take a lag of one year, i.e., $L(y) = y(t-1)$, so that equation (19) now can be stated as:

$$x(t) = s y(t-1)^n. \quad (20)$$

Equation (20) is the second substantive hypothesis.²

² It might be noted that if equation (16) is true, it implies $x(t) = k + 1/[m \log y(t)]$. This log function is not proposed as a causal hypothesis for the leader's interaction because it ignores the asymmetry in leader-follower interaction which is crucial to this alternative model and it does not follow from an appropriate psychophysical generalization. One might be tempted to use Fechner's log function as a premise to derive this hypothesis, but Fechner's equation has been shown to describe the relationship between the magnitude of perceptual error and stimulus magnitude for *some*, not all modalities (cf. Eisler, 1963; Shinn, 1974; Stevens, 1962). It does not describe the relationship between perceptual magnitude and stimulus magnitude, the kind of generalization required by this model of arms races.

Lagging the leader's interaction might suggest a difference equation model of the process. How-

THE DATA

The seven data sets used here involve different arms races—pre-World War I, pre-World War II, the cold war between the U.S.S.R. and the United States—and also different through-time measures of armaments—expenditures, warlike work time and weapons counts.

Expenditures by the Entente and Alliance

The data set which Richardson (1960: 87-97) used as a preliminary test of his theory involved armament expenditures by the Entente (France, Russia and Great Britain) and the Alliance (Germany, Austria-Hungary and Italy) from 1907 through 1914. Richardson collected the data himself and converted the expenditures in various national currencies into pounds sterling. He also made adjustments so the budget years all corresponded to one another.

Warlike Work Time: The Axis versus the Allies

Richardson (1960:114-20) also collected expenditures data on the arms race prior to World War II. He ran into trouble, however, because this period spanned the Depression, and the currencies of some of the nations fluctuated wildly in value. Also France, Germany, and perhaps some other nations hid their armament expenditures in budgets of several ministries, made false statements about armament expenditures or simply refused to give information.

In an effort to circumvent these difficulties, Richardson (1960:136-44) developed a measure of warlike work time for four Axis nations (Germany, U.S.S.R., Japan and Italy) and six Allied nations (France, China, Britain, United States, Poland and Czechoslovakia) for the 1927-1939 period. The measure is not without defects, but economist Kenneth Boulding (Richardson, 1960: vii) characterized

ever, our model is based on perceptual equations and perception is a continuous, not a discrete process. Also, intelligence information is accumulating continuously and decision makers, (like the National Security Council and the Joint Chiefs of Staff) meet weekly and make decisions, not in discrete yearly intervals but aperiodically, if not continuously.

COLON

Richardson's efforts as bringing "order into a field where disorder is usually regarded as supreme." These data indicate that the arms race began in 1934 (before that the data fluctuate as in an equilibrium). We excluded the U.S.S.R., because of its difficulty in deciding whether it was Axis or Ally, and China, because of its internal wars during that period. Work time on actual wars by Italy (in Abyssinia) and Japan (in China) also was excluded.

Nuclear Explosions and Weapons Counts: U.S. and U.S.S.R.

Data are available on several arms races between the United States and the U.S.S.R. since World War II (Stockholm Peace Research Institute, 1973; 1974; Institute of Strategic Studies, 1970; 1974). During that period, several important weapons were developed and the two nations raced to gain superiority in each. Such weapons were nuclear warheads, ballistic missiles (intercontinental and submarine-launched) and photographic and electronic satellites. However, their selection here was not arbitrary; each is a key component of the essential cold war armament effort and together they are the most deadly weapons system ever devised.

In the case of nuclear explosions, the gauge of armaments is not a weapons count but a measure of accumulated warlike work on the development of the most destructive weapon ever, the nuclear bomb. The data on nuclear explosions involve two races, one from 1949 through 1958, before the 1959-1960 nuclear test moratorium, and one afterward, from 1961-1973. These data seem to be accurate because they are based on seismographic readings or, in the case of some of the early explosions, radioactive fallout. In spite of that, the exact years of some 53 explosions were not given. In those instances, we added them to the last of the possible years.

Ballistic missiles were developed as the prime vehicle for delivering nuclear warheads. They are launched either from silos (ICBMs) or from submarines (SLBMs). The count is a total of both types during the period of mutual increase in inventories.

To some, photographic and electronic reconnaissance satellites may not seem like much of a weapon, but they are the eyes which accurately pinpoint potential nuclear targets in the other country, as well as monitor the other's warlike and industrial activity. Thus, they are extremely important weapons when used in conjunction with ballistic missiles and nuclear warheads.

Richardson's model was designed to describe arms races. Therefore, it follows that the best or most direct measures to use in evaluating his model are counts indicating the quantity and quality of the weapons. His use of expenditures and work time were, at best, indirect indexes of numbers and quality. The total number of ballistic missiles is a measure of the quantity of one very crucial cold war weapon and as a measure it can increase as it has for the U.S.S.R. (at least until 1973) or remain constant (as it has for the U.S. for at least seven years), or it can decrease (missiles can be destroyed by their owners). The cumulative numbers of photographic and electronic reconnaissance satellites were used, like nuclear explosions, not as weapons counts but as indexes of quality—i.e., level of weapons development.

ANALYSIS

Equation (10), the solution to Richardson's model, takes the form of a linear regression equation. The coefficient matrices in (10), A^* and B^* , were estimated using ordinary least squares (OLS).³ Because A^*

³ Applying OLS entails the usual assumptions (Blalock, 1972:429-33; Johnston, 1972:121-2). The cross-lagged model employed here may have a more complex error structure than is assumed by OLS. While the deterministic equations specified by Richardson do not allow for any error, we have assumed an additive error term in the estimating equations to allow for random (non-accumulating) measurement errors. This assumption is particularly vulnerable to problems of autocorrelation. Durbin-Watson tests (Johnston, 1972:251-3) failed to reject the null hypothesis of no autocorrelation in all but the electronic satellites race. Generalized least squares estimates that adjust for autocorrelation (Johnston, 1972:259-65) were not computed because they would consume an additional degree of freedom, too

and B^* are functions of the structural parameters of the differential equations (A and B), the method proposed by Singer and Spilerman (1976) was used to obtain estimates.⁴ From equations (9) and (10):

$$B^* = e^B \text{ or } B = \ln(B^*) \quad (21)$$

However, equation (21) yields an estimate of B from an empirically estimated B^* only under specific necessary conditions (Singer and Spilerman, 1976:10-4) which were satisfied except for the ballistic missiles race. For the six races that satisfied the necessary conditions, B was estimated using Sylvester's formula (Singer and Spilerman, 1976:18):

$$\hat{B} = \ln(\hat{B}^*) = \frac{\ln(\hat{\lambda}_1)}{\hat{\lambda}_1 - \hat{\lambda}_2} (\hat{B}^* - \hat{\lambda}_2 I) + \frac{\ln(\hat{\lambda}_2)}{\hat{\lambda}_2 - \hat{\lambda}_1} (\hat{B}^* - \hat{\lambda}_1 I), \quad (22)$$

if $\hat{\lambda}_1 \neq \hat{\lambda}_2$, where the $\hat{\lambda}$'s are eigenvalues of \hat{B}^* . Given that estimate of \hat{B} , \hat{A} was obtained from the definition of A^* :

$$A^* = (B^* - I)B^{-1}A \quad (23)$$

$$\text{thus, } \hat{A} = \hat{B}(\hat{B}^* - I)^{-1}\hat{A}^*. \quad (24)$$

This method for obtaining an estimate of A assumes that \hat{B}^{-1} and $(\hat{B}^* - I)^{-1}$ exist—i.e., $a\beta - kl \neq 0$. An estimate of A was found for every race in which an estimate of B was found—i.e., for all but the ballistic missiles race. Since the ballistic missiles race lacked empirical solutions to the differential equations, a difference equation approach, which implies

$$\hat{B} = \hat{B}^* - I, \quad (25)$$

$$\hat{A} = \hat{A}^*, \quad (26)$$

where \hat{B}^* and \hat{A}^* are estimated using equation (10), was used to obtain the estimates presented.⁵

As mentioned, part of the appeal of Richardson's theory has been its implications for the stability of arms races (e.g., Richardson, 1960:22-3; Blalock, 1969:106-9; Coleman, 1968:448-9). According to the model, stable arms races approach an equilibrium point defined as the point at which neither country's arms stores are changing:

$$\frac{dy}{dt} = \frac{dx}{dt} = 0. \quad (27)$$

Furthermore, once the equilibrium is reached, the system adapts to random shocks that move one country or the other off its equilibrium point and returns the arms race to equilibrium levels. Unstable arms races, on the other hand, escalate indefinitely according to Richardson's equations; the result being war or bankruptcy (Richardson, 1960:61).

Stability is a function of the relative sizes of the "insecurity" and "fatigue" parameters. In general, a system of linear differential equations will be stable if the eigenvalues of B have negative real parts (Boyce and DiPrima, 1969:390). In the 2 x 2 case being considered here, a race is stable if (Blalock, 1969:106-9; Coleman, 1968:448-9):

$$a\beta - kl > 0, \quad (28)$$

$$a + \beta > 0. \quad (29)$$

high a price to pay to correct a problem affecting less than two percent of the total variance in a relatively short series (seven years). Another potential problem is simultaneity bias which leads to under-identification, but Blalock (1969:83-4) shows that simultaneity bias in cross-lagged models is zero when autocorrelation of the errors is insignificant.

⁴ Although the discussion by Singer and Spilerman (1976) is limited to continuous-time Markov processes, their derivations apply to any matrix equation of the form:

$$B^* = e^B.$$

⁵ Derivation of the difference equation solution and parameter estimates obtained from that solution for all arms races are available from the authors upon request. In general, parameter estimates obtained using the difference equation approach were not equal to those obtained using the differential equation approach, but the signs of the parameter estimates were the same in all but one case. Furthermore, since both solutions are based on equation (10), R^2 values are identical. Thus, the conclusions reached in this paper would not change if a difference equation approach were substituted for the differential equation approach developed by Richardson and employed here.

The values of x and y at equilibrium can be obtained by setting equations (5) and (6) to zero and substituting terms if the conditions in equations (2*) and (29) are satisfied:

$$y = (g/a) + (k/a)x \quad (30)$$

$$x = (h/\beta) + (l/\beta)y \quad (31)$$

$$y^* = (\beta g + kh) / (a\beta - kl) \quad (32)$$

$$x^* = (lg + ah) / (a\beta - kl) \quad (33)$$

if $a \neq 0$; $\beta \neq 0$; $a\beta - kl \neq 0$, where y^* and x^* are the predicted equilibrium values of y and x , respectively. Equations (28) through (33) allow a further test of Richardson's model since we can determine whether or not unstable races resulted in wars, and we can compare the predicted equilibrium values with the observed stopping points for stable races.

Analyses for the exponential and power functions predicted by the second theory were done using a nonlinear regression program based on the Fletcher-Powell (1963) optimization technique. Both equations are just-identified because they can be log transformed so they are linear in the parameters (Christ, 1966:331-4).

RESULTS AND DISCUSSION

The relative adequacy of the two models will be gauged using four criteria: (1) the overall fit of the derived equations to the arms race data, (2) parsimony, (3) the reasonableness of the parameter estimates and (4) the predictions about war and armed truce. Other things being equal, relative superiority on any one of these cri-

teria is sufficient grounds for choosing between the models.

Comparison of Fit

The R^2 values gauging the fit of the alternative models to the seven sets of arms race data are given in Table 1. Since the linear equations have one more independent variable than the power and exponential equations, the R^2 values were adjusted for degrees of freedom (Johnston, 1972: 130). In general, the fit of all of these models to the data is quite good: only three R^2 values are less than .90. However, Richardson's linear, additive equation models the leader's interaction slightly better on the average than the power function; the *mean* R^2 is .977 versus .974. In contrast, the exponential equation models the follower's interaction somewhat better on the average than does Richardson's linear equation: the *mean* R^2 is .986 versus .957. Thus, neither Richardson's linear, symmetric model nor the alternative curvilinear, asymmetric model is preferred on the basis of fit alone.

Comparison of Parsimony

Richardson's linear, additive model has six parameters (three in each equation), and the asymmetric, curvilinear model has only four (two in each equation). Since the fit of the two models is approximately the same, relative parsimony could be important in making a choice. However, we must consider two more criteria before making a decision—the reasonableness of

the parameters and the predictions about war and armed truce.

Comparison of Parameter Estimates

The linear model. The parameter estimates for the linear model are given in Table 2. Although Richardson discussed conditions under which the insecurity parameters k and l (1960:12) or the grievance parameters g and h (1960:16) may be negative, he clearly expected positive values for all parameters under the antagonistic circumstances of the pre-World War I, pre-World War II and, presumably, the cold war arms races analyzed in Table 2 (Richardson, 1960:13-37, 61-9). Thus, the negative parameters in Table 2 are problematic for Richardson's model. There is at least one problematic coefficient for six of the seven arms races.

Many of the negative coefficients are estimates of g and h , the grievance parameters. Richardson (1960:16) observed that a negative grievance parameter can arise for one side in an arms race when at the onset "the prevailing mood of that side is contentment." Taken at face value, the findings indicate that the Entente and the Alliance both began their pre-World War I race with contentment coefficients (-6.9 versus -41.9) and that the Axis and the Allies began their pre-World War II arms race with grievance coefficients (19.8 versus 4.9). Both the U.S. and the U.S.S.R. started the first nuclear explosions race

with large coefficients of contentment toward each other (-13.0 versus -15.4), but started the second nuclear explosions race (*a year or so before the atmospheric test ban treaty was negotiated*) with large grievance coefficients (106.8 versus 18.7). The U.S. and U.S.S.R. photographic satellites race began with a grievance coefficient (1135.0) for the U.S. and a contentment coefficient (-315.5) for the U.S.S.R. Similarly the electronic satellite race began with a 20.0 grievance coefficient for the U.S. and a -41.3 contentment coefficient for the U.S.S.R. The difference-equation solutions for the ballistic missiles race give both the U.S. and U.S.S.R. grievance coefficients (273.6 versus 46.4). This is an unrealistic pattern of mixed results that makes little if any sense, given our historical knowledge of conditions surrounding the beginnings of these races.

Just as surprising are the non-positive estimates of k and l , the insecurity parameters, which appear in all but the expenditures (1909-1914) and ballistic missiles (1961-1967) races. Negative insecurity coefficients indicate that the party in question is responding to increases in the other's armaments with security, not insecurity, and thus it decreases rather than increases its armaments each round as a result of the other's armament increases. The results indicate that the Axis (-8.31) in the pre-World War II arms race, the U.S.S.R. (-6.81) in the first nuclear explosions race,

^a The eigenvalues of the estimating matrices for the arms races are complex conjugates.

^b The determinant of the estimating matrix is less than zero, therefore no solution to the differential equation exists. Solution to difference equation formulation is substituted (see footnote 5).

both the U.S. (-0.004) and the U.S.S.R. (-0.45) in the second nuclear explosions race, and the U.S. (-5.38) in the photo satellite race had "security" rather than "insecurity" coefficients—i.e., were decreasing their armaments as a function of their racing partner's increase in armaments. The insecurity coefficient of the U.S. in the electronic satellites race was zero, which implies the U.S. simply was not responding during that race to accumulative increases in the U.S.S.R.'s electronic satellites.

Estimates of α and β , the "fatigue" parameters, are also negative in some instances. Richardson (1960) did not mention this possibility, but negative values of α and β imply that spending money for arms does not result in a side's becoming fatigued, with its expenditures slowing down the further accumulation of armaments—but that in each round the expenditures create economic energy which increases the rate of arms accumulation. The data imply this mysterious process occurred with the Axis (-1.56) in the pre-World War II race, with the U.S.S.R. in the first (-8.97) and second (-0.07) nuclear explosion races, and with the U.S. (-2.14) in the photographic satellites race. Keynesian economic theory might predict such "pump priming" results for market economies if not planned economies like the U.S.S.R. However, this is not an explanation, because the postulated effects occurred in some races but not others. Why did the expenditures for armaments result not in energy, but fatigue—a slowing down of expenditures—for the Entente (0.56) and the Alliance (0.44) in the pre-World War I race, the Allies (2.23) in the pre-World War II race, the U.S. in the first (6.35) and second (0.17) nuclear explosion races, the ballistic missiles race (0.59) and the electronic satellites race (0.29) and the U.S.S.R. in the ballistic missiles race (0.60) and the satellite races (2.15 and 0.36)?

Historically and substantively, this pattern of mixed—some positive and some non-positive—grievance, insecurity and fatigue coefficients make little if any sense. Rather the unreasonable mixture is an indication that Richardson's model may be misspecified, that he inadvertently imposed

Figure 1. Annual armament expenditures for Entente and Alliance nations 1907-1914 in millions of pounds sterling. The dashed line represents the exponential function given in the figure. (Data from Richardson, 1960.)

a linear model on data generated by a curvilinear process (see Figures 1-5). The question is, does the asymmetric, curvilinear model behave more consistently?

The curvilinear model. In evaluating this model, several criteria are used. First, to

relationship. Also, the asymmetrical predictions are based on the assumption that different experimental generalizations—i.e., psychophysical equations about perception and, hence, reactions to stimuli—describe the leaders' and followers' respective interactions in arms races. Consequently, for the test of the model's asymmetry to be positive, the predicted exponential equation should describe the followers' interactions better than the power function, and the predicted power function should describe the leaders' lagged interaction better than the exponential.

First, all of the parameter estimates in the equations predicted for both the followers and the leaders in the top and bottom of Table 3 are positive for all seven races. The curvilinear model passes this test.

Second, all of the compound rates in the top of Table 3 for the exponential equations predicted for the followers are somewhat larger than zero. Some might question the 0.00134 compound rate estimated for the ballistic missiles race (see Figure 5). While there is some noise, it is typically exponential with as much curvature as is found in the plot of the photographic satellite race, Figure 3. This is because the process is compounded 1,710

times in the ballistic missiles race. The compound rates reflect the insecurity produced by one armament unit. In this instance, one ballistic missile does not produce much insecurity, hence the compound rate is small. The exponents of the power functions predicted for the leaders in the bottom of Table 3 are all quite substantial, ranging from 0.122 for the U.S. in the electronic satellites race to 2.38 for the Axis in the pre-World War II race. So everything considered, the curvilinear model also passes this test.

Third, in the top of Table 3, each exponential equation exhibits a better fit than the corresponding power equation, as predicted for the followers' interactions in arms races. In the first nuclear explosions race and the electronic satellite race, the r^2 for the power function is greater than that for the exponential function. However, in those instances, near zero scaling constants combine with large exponents for unreasonable results. In every instance for the leaders' interactions in the bottom of Table 3, the power equation does better than the exponential. Hence, the results indicate the curvilinear model passes the test for its asymmetry.

The r^2 values for the curvilinear model are somewhat less than .99 in four of the seven arms races: those involving years of warlike work, nuclear explosions and ballistic missiles. It should be remembered, however, that the model is based on the way the decision makers of the racing nations perceive and then react to the other

side's armaments. In these four races, the relevant information was secret and, hence, had to be obtained or estimated by intelligence agents. There is little reason to believe that these year-by-year intelligence reports are reliably represented by the more accurate (but still fallible) data analyzed here. Thus, we attribute the attenuated r^2 values obtained for these races to the unreliability of both perceptions and measures. For three of the races, the measurement is unquestionable: in the pre-World War I race, accurate expenditure data were published each year by the various nations and the quantity of launched photographic and electronic satellites are reliably detected by radar. In these three races, it is very significant that the r^2 values are virtually perfect (.994, .999 and .997, respectively, for the followers' interactions and .991, .992 and .996 for the leaders'). Notice also the plots for two of these races in Figures 1-4.

War and Armed Truce

We will now evaluate the alternative predictions of war or armed truce by the two models.

The linear model. Table 4 presents the stability-instability calculations based on the parameter estimates in Table 2. The stability conditions predicting armed truce, as given in equations (28) and (29), are that both $a+\beta$ and $a\beta-kl$ must be positive. The formulae for the equilibrium points (y^* , x^*) are given in equations (32) and

Table 4. Stability and Location of Equilibrium as Implied by Parameter Estimates for Richardson's Model

* Difference equation solution substituted (see footnote 5).

(33). The observed stopping points (y_T and x_T) are also presented.

According to these results, the first five arms races were unstable and therefore should have resulted in war. The first two did: World War I and World War II. The first nuclear and ballistic races ended with moratoriums or with one party just stopping. Thus, Richardson's model predicted war when it did not occur. The two satellite races appear to be stable as predicted by Richardson's model. However, they did not stop at the expected points. For example, in the photographic satellite race (1962–1973), the model predicts the equilibrium at a point when the U.S.S.R. had roughly 200 fewer satellites than they had put in orbit by 1973. Thus, these stability-instability predictions are partly correct and partly incorrect. Since they are a function of parameter estimates already shown to be unreasonable, their inaccuracy is not surprising.

The curvilinear model. This model implies that the origin ($y^*=0$, $x^*=0$) is the only equilibrium and that it is unstable (any movement will touch off an arms race among rivals). The exponent in the power function describing the leaders' interaction appears to gauge the leaders' aggressive intentions and, thus, predicts whether the outcome will be war or armed truce. To the extent the exponent is greater than 1.0, the leader proportionately increases its relative advantage (see equations [17] and [14]). On the other hand, to the extent the exponent is less than 1.0, the leader allows the follower to catch up. Maintaining or increasing the advantage by the leader (as when $n \geq 1$) appears to predict war and allowing the follower to catch up (as when $n < 1$) appears to predict a negotiated end to the race—an armed truce.

In the pre-World War I race, the exponent for the leader (the Entente) was 1.04, which apparently indicates only a moderate level of aggressive intent—more than enough to maintain the initial armament advantage. The beginning of that war seems to have been somewhat accidental, not the obvious responsibility of the Entente. However, their behavior signalled that their intentions were not necessarily defensive. They were aggressive enough to

more than maintain their relative advantages throughout the race, which may have communicated an unwillingness to live with an equitable balance of power.

The Axis, the leader in the pre-World War II race, increased their relative advantage each round by 2.38. This seems to signal an extreme level of aggressive intent, but no more than was contained in the speeches of their decision makers, nor more than was later evidenced in their *blitzkriegs* in Europe, Africa and the Pacific. Think of it—each year they increased their relative advantage by 2.38!

The U.S., the leader of the cold war arms races, in most instances signalled less and less aggressive intent in subsequent races. The 0.94 exponent for the second nuclear explosions race was higher than the 0.66 exponent for the first. However, the others progressively decreased to 0.62 for the ballistic missiles race, 0.28 for the photographic satellites race, and 0.12 for the electronic satellites race. In every instance, the U.S. allowed the U.S.S.R. to catch up, thus signaling that their intent was not aggression but a balanced armed truce.

In such arms races, there is another possibility. The follower can overtake the leader and thus turn the asymmetry around by refusing to stop: the former follower becomes the new leader and the former leader, the new follower. From that juncture, the race should reflect changed asymmetric patterns of interaction. The prospect is unlikely, however, when the balance involves a nuclear deterrent with a several-fold overkill capacity. Yet the nature of the balance probably has to be negotiated, as the U.S. and U.S.S.R. are finding out.

CONCLUSIONS

Using data from seven arms races we have completed four tests of Richardson's linear, symmetric model and the curvilinear, asymmetric model and are in a position to compare the two. (1) Both pairs of equations fit the data almost equally well. (2) The curvilinear model is more parsimonious. (3) The parameters of the linear model were mixed in sign in a non-

sensical pattern, the apparent result of attempting to describe what is clearly a curvilinear process with linear equations. The parameters of the curvilinear model were well behaved: the compound rate in the exponential equation for followers' reactions evidently gauges the insecurity produced by the arms unit in question, and the exponents in the leaders' power functions gauge the aggressive intent of the leader. (4) Concerning the seven predictions about war or balanced armed truce, Richardson's model made at least three which were in error. None of the predictions by the curvilinear, asymmetric model were incorrect. The inferences drawn from this fourth comparison are based partly on an empirical generalization and are, therefore, more guarded than the others. However, on three of four criteria, the results indicate the alternative model is preferable.

Richardson (1960:14) was quite frank about the tentativeness of his model: he followed Ockham's rule by trying out "the easiest formulae first." In his favor, some of the relationships in the pre-World War I race did approach linearity as may be noted in Figures 1 and 2. One might well question whether simultaneous linear, additive differential equations are the easiest, however. Nevertheless, they have been given a thorough try here and found wanting.

While incorporating certain features of Richardson's verbal paradigm, the alternative model was constructed using a different strategy.⁶ Instead of using ad hoc differential equations, the alternative model was built using experimental generalizations from psychophysics about the behavior of people. These generalizations probably would have delighted Richardson. He was the first social scientist to sense the

potential importance of psychophysics for understanding social behavior. A number of classical theorists such as Mead and Weber have argued the importance of perceptions, but they never had the insight about using psychophysical equations as perceptual premises in social theory. This was an attempt to use these perceptual generalizations to construct a middle-range theory or model of the way a particular conflict, an arms race, is escalated through time. We are not disappointed.

The model does have some very important policy implications since it apparently identifies the characteristics of arms races which predict war or the possibility of a balanced, armed truce. It also suggests there is no stable arms race which will eventuate automatically in an equilibrium level of armaments. It does identify a class of arms races that can eventuate in a balance, but the armed truce may not occur automatically. Very likely, it must be negotiated.

In any event, this is a subject for further research. It would be helpful if the model and all of its implications were evaluated further on data sets generated in additional races. That is one path to a better understanding of these very important phenomena.

APPENDIX A Arms Race Data Sets

Armament Expenditures Race 1907-1914

Expenditures in Millions of Pounds Sterling

Year	Entente	Alliance
1907 ^a	151.8	83.9

1912	197.8	113.9
1913	215.1	127.2
1914 ^b	239.2	150.9

(Source: Richardson, 1960:87)

⁶ We tested an additional model which was not built on Richardson's interaction assumptions; the racing nations simply increased their armaments as decaying exponential functions of time— $dy/dt=k(n-y)$ and $dx/dt=l(m-x)$. We attempted to fit the solutions of these equations to the relevant data for the seven arms races, using SPSS nonlinear regression, the Fletcher-Powell nonlinear regression and an iterative program based on a log transformation. None of these programs converged to unique solutions, so the model was rejected.

COMMENTS

POPULISM AND LYNCHING IN LOUISIANA*

(COMMENT ON INVERARITY, ASR
APRIL, 1976)

From its beginnings in the work of Durkheim (1893), social solidarity has been a central concept in sociology. Indeed, the functionalism of Parsons and the functional structuralism of Merton can be seen to follow in this tradition (cf. Turner, 1974). More recently, Blau (1974) in his "parameters of social structure" and Ekeh (1974) in his analysis of social exchange theory have attempted to synthesize processes of differentiation and integration in society.

This comment addresses one recent attempt (Inverarity, 1976) to examine the causes and consequences of solidarity. Although this comment points out a number of methodological and conceptual problems, it is intended in no way to detract from what can be described as a highly original operationalization and test of mechanical solidarity. In fact, a portion of the reanalysis of Inverarity's data indicates that the data support the theory to a greater extent than reported in certain instances.

Inverarity's First Causal Model

The principal model tested by Inverarity consists of three causes of mechanical solidarity and its indicators (see Figure 1). Consider first the findings reported by the author. Using the procedures developed by Jöreskog et al. (1970), Inverarity (1976: 274) claims that the model produced a χ^2 goodness-of-fit of 11.61 with six degrees of freedom and $p > .05$. The author then concludes:

Since the chi-square value in this case is not significant, there is no major difference between observed and expected values. . . .

Failure to reject the model on statistical grounds means that we can adequately account for the configuration of observed relationships between lynching and five characteristics of the parishes by a model specifying three characteristics of a cause of the unmeasured variable mechanical solidarity

and two characteristics as consequences of solidarity. (Inverarity, 1976: 275)

The interpretation of the χ^2 test by Inverarity is erroneous in this case, and it leads the author to propose a conclusion opposite to that indicated by the data. Given the results reported by the author, one should reject the model and conclude that the structure of causal relationships does not support the theory. The χ^2 test in question is a test of one's model against the most general alternative that the variance-covariance matrix is any positive definite matrix (cf. Jöreskog and van Thillo, 1972: 8). The probability, p , for the χ^2 test is the probability of obtaining a χ^2 value larger than the value actually obtained, given that the hypothesized model is true. Consequently, the larger the value of p , the better the fit. As a rule of thumb, Lawley and Maxwell (1971: 42) suggest that one fails to reject models where the value of χ^2 is below the ten percent significance level, i.e., when $p > .10$.

Actually, the causal analysis performed by Inverarity contains a number of errors, and the data can be shown to support the theory to a degree better than that reported. Although the model proposed by Inverarity will be modified below in order to better represent Durkheim's (1964) theory of solidarity, it will prove informative to reanalyze the data. Inverarity incorrectly applied Jöreskog's procedures by failing to treat the model of Figure 1 as a true multiple indicator-multiple cause (MIMIC) model. In order to use Jöreskog's procedures for the MIMIC model, certain assumptions and alterations must be made to the structural equations representing the causal model. First, the correct equations for the model of Figure 1 must be written as

$$(1) \eta = (\gamma_1 \ \gamma_2 \ \gamma_3) \begin{pmatrix} \xi_1 \\ \xi_2 \\ \xi_3 \end{pmatrix} + \zeta$$

$$\begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} = \begin{pmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \end{pmatrix} \eta + \begin{pmatrix} \epsilon_1 \\ \epsilon_2 \\ \epsilon_3 \end{pmatrix}$$

$$\begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \xi_1 \\ \xi_2 \\ \xi_3 \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

* The author would like to thank Professors Robert F. Boruch, Northwestern University, and Ronald S. Burt, University of California, Berkeley, for pointing out errors made in an earlier version of this comment.

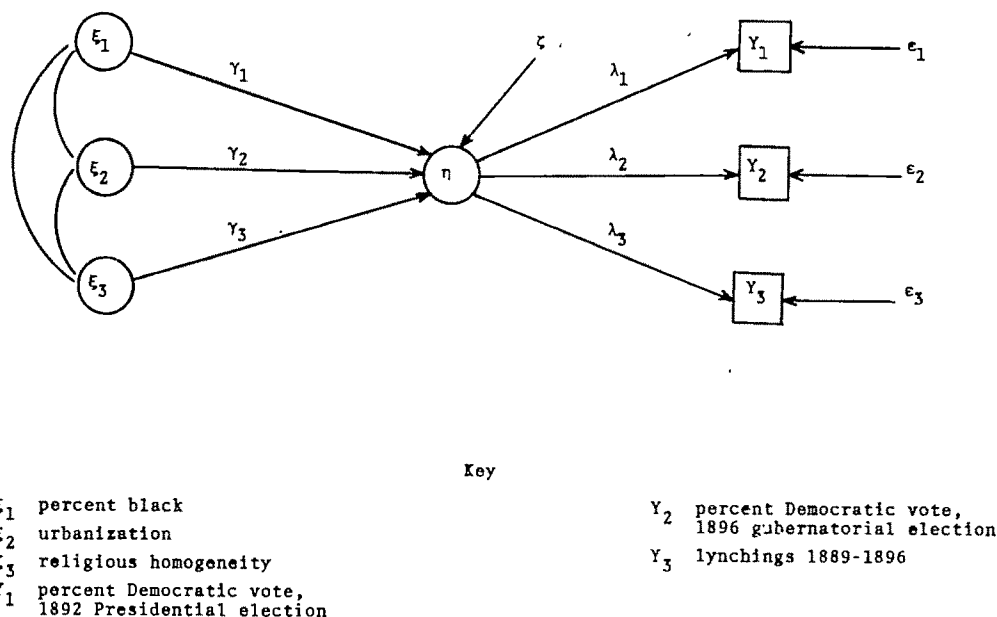

Figure 1. Causal Model for Mechanical Solidarity after Inverarity (1976: 271)

Second, in order to remove an indeterminacy in the structural parameters, the variance of the theoretical construct, mechanical solidarity, must be assumed normalized at unity (cf. Jöreskog and Goldberger, 1975: 632). Third, the degrees of freedom for the MIMIC model must be calculated as $q(p-1)+p(p-3)/2$ where q is the number of observable exogenous variables and p is the number of observable endogenous variables. Finally, it is necessary to treat the correlation matrix as a dispersion matrix when using Jöreskog's procedures to test a MIMIC model.

Using the computer program devised by Jöreskog and van Thillo (1972), LISREL II, Inverarity's first model was reanalyzed as shown in Table 1. Notice that the χ^2 , degrees of freedom, p value, and parameter estimates differ from those reported by Inverarity. Although the model fits the data somewhat better than the one reported by Inverarity, one must still reject the proposed structure. An examination of the parameter estimates indicates that the effects of both urbanization and religious homogeneity upon mechanical solidarity (i.e., γ_2 and γ_3) are not twice their standard errors and hence might be dropped from the model. Alternatively, better measures of these variables could be found. These last points illustrate why it is important to calculate standard errors of parameter estimates in sociological research and how they may be used in a diagnostic and model-building sense.

A final point to note about the analysis of Inverarity is that the low sample size ($n=59$)

may cause a greater degree of variability than desirable in one's parameter estimates. This is the result of the well-known phenomenon that maximum likelihood procedures are notoriously unstable for low sample sizes. In these cases, one might consider correcting the χ^2 estimate using a correction factor such as Box's (cf. Lawley and Maxwell, 1971: 36). For an excellent discussion of external and internal validity and related problems with the χ^2 test, see Burt (1973: 146-50).

Inverarity's Second Causal Model

The second model tested by Inverarity is identical to the first except that a fourth exoge-

Table 1. Parameter Estimates, χ^2 Goodness-of-Fit and Standard Errors for the Model of Figure 1 and the Data of Inverarity (1976)

Parameter	Maximum Likelihood Estimate	Standard Errors	Standardized Estimates
γ_1	1.085	.299	.723
γ_2	.166	.191	.111
γ_3	.165	.195	.110
λ_1	.371	.097	.556
λ_2	.575	.140	.863
λ_3	.208	.097	.312
θ_{ϵ_1}	.831	.087	.831
θ_{ϵ_2}	.505	.153	.505
θ_{ϵ_3}	.950	.090	.950

$\chi^2=11.20$, $df=6$, $p=.08$.

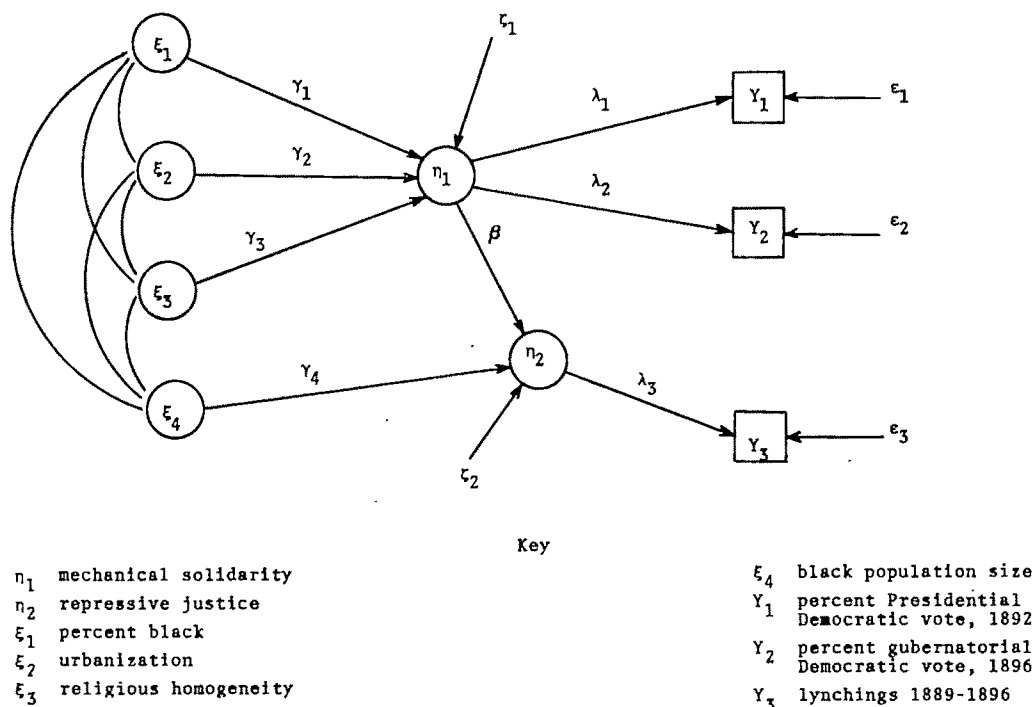

Figure 2. A Causal Model Respecifying the Relationships among the Causes and Consequences of Mechanical Solidarity

nous variable, black population size, is introduced as a cause of repressive justice. Strictly speaking, this is not a MIMIC model and should not be treated as such. Before presenting the reanalysis of Inverarity's second model, it will prove helpful to discuss the specification of the model. In both of his models, Inverarity represents repressive justice as an indicator of mechanical solidarity. This practice is somewhat misleading, and there are conceptual reasons why one might not want to do this. It is important to make a distinction between a causal relation between variables on the one hand and the relationship between a variable and its indicator(s) on the other. The former is a relationship between theoretical constructs, while the latter is a relationship between a theoretical construct and its operationalization(s). Since Inverarity desired to test the effect of mechanical solidarity upon repressive justice, this relationship should have been represented as one between theoretical variables rather than between a theoretical variable and its indicator, as was done in the original analysis. A second point about the specification of the model deals with the two causes of mechanical solidarity, percent black and black population size. Since a common element exists in both of the "causes," they are not separate variables, by definition, and should not be modeled as such. One or the other should have been omitted.

With these caveats in mind, Figure 2 represents a respecification of Inverarity's second model showing repressive justice as a theoretical variable. Unfortunately, the parameter relating mechanical solidarity to repressive justice, β , cannot be estimated in its present form because the model is not identified.¹ The parameter β cannot be separated from λ_3 as the model stands. In order to remove this indeterminacy, one can model lynchings as an infallible indicator of repressive justice. The following represents the structural equations for this modification of Figure 2:

$$\begin{pmatrix} 1 & 0 \\ -\beta & 1 \end{pmatrix} \begin{pmatrix} \eta_1 \\ \eta_2 \end{pmatrix} = \begin{pmatrix} \gamma_1 & \gamma_2 & \gamma_3 & 0 \\ 0 & 0 & 0 & \gamma_4 \end{pmatrix} \begin{pmatrix} \epsilon_1 \\ \epsilon_2 \\ \epsilon_3 \\ \epsilon_4 \end{pmatrix} + \begin{pmatrix} \zeta_1 \\ \zeta_2 \end{pmatrix}$$

$$\begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} = \begin{pmatrix} \lambda_1 & 0 \\ \lambda_2 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \eta_1 \\ \eta_2 \end{pmatrix} + \begin{pmatrix} \epsilon_3 \\ \epsilon_2 \\ 0 \end{pmatrix}$$

$$\begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \epsilon_1 \\ \epsilon_2 \\ \epsilon_3 \\ \epsilon_4 \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

¹ This was pointed out to me by Professor Ronald Burt.

Table 2. Parameter Estimates, χ^2 Goodness-of-Fit and Standard Errors for the Model of Figure 2 and the Data of Inverarity (1976)

Parameter	Maximum Likelihood Estimate	Standard Errors	Standardized Estimates	Standard Errors
γ_1	1.030	.288	.707	.197
γ_2	.122	.181	.084	.124
γ_3	.148	.186	.101	.128
γ_4	.374	.119	.375	.120
β	.134	.091	.197	.133
λ_1	.377	.096	.550	.140
λ_2	.608	.149	.887	.217
θ_{e_1}	.835	.087	.835	.087
θ_{e_2}	.462	.186	.462	.186
$\psi^2_{\eta_2}$.789	.148	.795	.149

$\chi^2=10.31$, $df=8$, $p=.24$.

Table 2 presents the parameter estimates, χ^2 , degrees of freedom, and p value for this model where it can be seen that the model fits the data reasonably well. However, notice that the estimates for the effects of both urbanization and religious homogeneity upon mechanical solidarity and the effect of mechanical solidarity upon repressive justice are not at least twice their respective standard errors, providing evidence for rejection of the model and Inverarity's hypothesis.

One final comment is in order regarding the relative impact of various causal paths in the models. When comparing the relative magnitudes of causal paths for the same population of individuals, one should use standardized parameter estimates (cf. Tukey, 1954; Wright, 1960; Blalock, 1967a; 1967b). Comparing the relative impact of mechanical solidarity on repressive justice with the impact of black population size in Figure 2, one sees that the former is about 53 percent as large as the latter. Similarly, comparing the impact of mechanical solidarity upon repressive justice across Figures 1 and 2, one sees that the former is about 1.58 times the latter. These findings tend to invalidate Inverarity's (1976:276) assertion, "When black population size is explicitly considered, the estimated impact of mechanical solidarity on lynching is cut by more than half."

SOUTHERN VIOLENCE AND THE
POLITICAL PROCESS

(COMMENT ON INVERARITY, ASR
APRIL, 1976)

A recent work by Inverarity (1976) brilliantly employed sophisticated theory and methodology to examine the manner in which disturbances in a particular society, i.e., Louisiana between 1889 and 1896, influenced the level of repressive justice in the society, as measured by lynching incidents in the society over this time period. The article illustrated how social investigators might employ limited historical data to test the validity of social theories.

However, there are a number of problems with Inverarity's findings for the case of Louisiana and his exposition of the Durkheimian theory. First of all, this author questions the basic substantive premise of the article.

Southern whites in the 1890s experienced a boundary crisis analogous to the three that Puritan Massachusetts experienced during the seventeenth century. Reconstruction consolidated the two classes of Southern whites into a one-party system, but this unity was broken by a wave of agrarian radicalism (Inverarity, 1976:268).

In order to establish a causal linkage between Populism and lynchings, a plot of the frequency of lynching incidents in Louisiana over the period 1889 to 1900 was presented (Inverarity, 1976:267), and it was found that lynching incidents peaked during the election years when the Populists were most politically active in the state.

It seems reasonable to suppose that the crises would be most severe in election years and that, consequently, this will be revealed in the lynching rate. Thus, in the three election years (1892, 1894 and 1896) the average was 17 incidents per year. Moreover, the sharpest increase in lynchings occurs in 1896, the year of the most bitter contest in the gubernatorial election (Inverarity, 1976:268).

The previous argument assumes a zero time lag between Populist political activity and lynching activity, an assumption that will be accepted in this piece. In order to examine further the cross-sectional and longitudinal patterns of lynchings in this time period, let us differentiate the South into two subregions and then examine lynching patterns in these two subregions, as well as the remainder of the nation, between 1889 and 1917. Recent studies (Cosman, 1966; Matthews and Prothro, 1966:169-72; Strong, 1971) have shown that the eleven states of the old Confederacy may be differentiated into states in the upper South (i.e., Arkansas, Florida, North Carolina, Ten-

nessee, Texas and Virginia) and the deep South (i.e., Alabama, Georgia, Louisiana, Mississippi and South Carolina). The pre-Civil War plantation system was concentrated within the states of the deep South, and historically these states tended to have a low degree of urbanization and a large nonwhite population concentration in their rural areas. By contrast, the plantation system was less developed in the upper South, and these states tended to have a relatively low nonwhite population in their rural areas. An examination of the number of lynchings in the three areas between 1889 and 1917 (N.A.A.C.P., 1969) indicates that the highest number of lynchings occurred in the deep South, while the lowest number of lynchings occurred in the remainder of the nation. Also, in all three areas, lynching incidents reached some maximum value in the time period 1890 to 1900 and then fell off. This national and regional pattern of lynchings raises questions about Inverarity's (1976) assumption that the falloff in lynching incidents in Louisiana after 1896 indicated that a reunification of the white class groups in the state was occurring.

In order to relate further the Louisiana pattern to that of other similar areas, let us examine changes in lynching incidents in all states of the deep South between 1889 and 1917. As can be seen from Table 1, there were sharp variations as to when lynching incidents peaked in the five states of the deep South in this time period. For example, in Mississippi they peaked in 1891 and then proceeded to decline, whereas in Georgia they remained at a relatively high level until 1911. In Alabama, a state with a strong Populist movement, they were high in both 1892 and 1896, but they reached their peak in 1897. The data in Table 1 for the five Southern states do not support the position that Populism had a similar effect on lynching patterns within these five states, an effect one would expect if the Inverarity (1976) model were correct, given the similar cultural history of these five states and the relative strength of Populism in them.

Another difficulty with the article involves the conceptualization and testing of the theoretical model. The work is concerned essentially with determining whether changes in the level of mechanical solidarity in a society leads to a growth of repressive justice within the society. In the article, Louisiana society is differentiated in terms of county units, the level of mechanical solidarity is measured indirectly from three indicators (percent black, the degree of urbanization and the extent of religious homogeneity in the county) and the level of mechanical solidarity then is related to the

Table 1. Frequency of Lynching Incidents in the Deep Southern State between 1889 and 1917

Year	Lynching Incidents					
	Total Incidents	Alabama	Georgia	Louisiana	Mississippi	South Carolina
1889	50	6	8	9	22	5
1890	36	6	12	6	9	3
1891	57	13	8	13	22	1
1892	61	14	13	17	9	5
1893	42	12	7	8	9	6
1894	54	10	14	13	13	4

level of repressive justice in the society. It seems to this author that Erikson's theory does not lead to the conclusion that during a "boundary crisis" the level of mechanical solidarity within a society will have a positive impact on the level of repressive justice within the society. Instead, it implies that *changes* in the level of mechanical solidarity within a society during a "boundary crisis" will have an impact on the level of repressive justice within the society. The Erikson model is concerned with the influence of dynamic changes in the society upon the level of repressive justice in the society. The article assumes that within a society undergoing a "boundary crisis" the level of repressive justice will be greater in areas of the society with a higher level of mechanical solidarity. However, using Erikson's theory one also might argue that under these circumstances the portion of the society that possesses a higher level of mechanical solidarity should be less influenced by these disruptions and should thus experience smaller changes in its level of repressive justice, a result in contra-

diction with the findings of Inverarity's (1976) work.

This author would maintain that an alternate model developed by Snyder and Tilly (1972) to understand collective violence can be employed to explain lynching behavior in Louisiana and the remainder of the South. Snyder and Tilly (1972) were concerned with developing models to explain changes in the level of collective violence in France between 1830 and 1960. Rather than maintaining that lynching represents a form of repressive justice, let us define it as a form of collective violence.¹ Given this definition of lynching,

¹ In their work, collective violence is characterized in the following manner: "Our measure of collective violence is the estimated number of participants in continental France as a whole. 'Disturbances' are continuous interactions involving at least one group of fifty or more persons in the course of which someone seized or damaged persons or objects over resistance" (Snyder and Tilly, 1972:522). Assuming that most lynch mobs were composed of

which is consistent with the definition of the previous authors, one then can employ their model, assuming that lynching rates in the South in the time period 1889 to 1917 were related to the overall rate of collective violence in the region. The previous authors maintained that the immediate causes of collective violence are *political*, in the sense that collective violence results from changes in the power relationships between groups of men.

We suppose that the principal, immediate causes of collective violence are political. Collective violence results from changes in the relationship between groups of men and the major concentrations of coercive power in their environments (Snyder and Tilly, 1972:520).

Lynching in the South tended to be aggression against lower class whites and blacks by other white class groups in the South. One political activity that might have been related to changes in the lynching rate could be the disfranchisement of the blacks and the lower class whites in the South in the period between 1890 and 1910. A precise test of the political model would require a specification of other relevant independent variables and a statistical analysis which relates changes in the lynching rate to these specified variables.

There is some fragmentary evidence available at the present time which lends support to the position that the disfranchisement process was related to changes in the lynching rate. First of all, with regard to the state of Mississippi, Kousser (1974:139-45) has shown that it was between 1889 and 1892 that a series of political maneuvers occurred in the state which essentially disfranchised all blacks and many lower class whites ("ignorant and vicious whites") from the electorate. As can be observed from Table 1, it was also in this time period that the peak number of lynching incidents occurred in the state.

The results from the state of Louisiana with regard to the disfranchisement of blacks and lower class whites were somewhat distorted by Inverarity (1976).

"The agrarian revolt, however, died quietly. . . . The Democrats adopted the policy of disfranchising the blacks. In effect, this policy shifted emphasis from economic interests back to racial status as the basis of political organization" (Inverarity, 1976:266).

more than fifty individuals, lynching by this definition would have to be considered a form of collective violence. In the previous study, most of the measured forms of collective violence were directed against the state, whereas most of the lynching incidents involved interactions between class and racial groups.

The above historical assertion by Inverarity is empirically inconsistent with a recent study of the disfranchisement process in Louisiana in this time period (Kousser, 1974:152-65). In fact, it was in the period from 1892 to 1896 that political disfranchisement actually occurred in the state, with the political process related to this process peaking in the years 1892, 1894 and 1896, the same years when lynching incidents peaked in the state. Thus, in 1892, the state legislature set up a constitutional commission to limit the electorate to those who paid poll taxes and could read or write; in 1894, the New Orleans Ballot Reform League proposed to eliminate fraud by disfranchising illiterates (blacks and lower class whites); in 1896, there was an attempt to pass a constitutional amendment limiting the vote, but this amendment was defeated in the state election in April of 1896. However, in the latter part of 1896, the Louisiana State Legislature passed a bill which essentially disfranchised most blacks and many lower class whites.

The registration act, which went into effect after January 1, 1897, cut the white registration by more than half and the Negro by 90%. The disfranchisement of almost all Negroes and many whites was, therefore, a *fait accompli* by the time of the constitutional convention (Kousser, 1974:162-3).

The previous statement raises serious questions about Inverarity's (1976) substantive conclusions. One can perform a crude test on the lynching data (N.A.A.C.P., 1969) for Louisiana to determine whether it was the Populist activity or some other factors, such as the disfranchisement process, which was related to the high level of lynching incidents in the state during the year 1896. In 1896, there were two aspects to the political struggle engaged in by the Populists. On April 27, 1896, there was a gubernatorial election in which the Republicans and the Populists formed a coalition to oppose the Democrats (Kousser, 1974:157), while on May 28, 1896, the Republicans and the Populists formed a coalition in an attempt to elect their senatorial candidate in the state legislature (Kousser, 1974:158-9). Assuming a zero time lag between political activity and lynching incidents and noting that the disfranchisement activity was occurring throughout 1896, one would predict either more lynching incidents between January 1st and April 28th, or more incidents between January 1st and May 28th, assuming that Populist activity was indirectly related to lynching behavior in the state. If there were not significantly more lynching incidents in either of the above periods, one could conclude that it might be something else beside the

Table 2. Goodness-of-Fit Tests for the 1896 Louisiana election Results in Relation to Lynching Incidents

Time Period	Actual Number of Lynching Incidents	Expected Number of Lynching Incidents
April 28, 1896 Gubernatorial Election *		
January 1, 1896–April 28, 1896	6	6.178
April 29, 1896–December 31, 1896	13	12.822
May 28, 1896 Senatorial Legislative Struggle **		
January 1, 1896–May 28, 1896	8	7.735
May 29, 1896–December 31, 1896	11	11.265

* Chi-square=.00756, df=1, $p>.900$.** Chi-square=.01531, df=1, $p>.900$.

Populist activity which explained the high number of lynching incidents in the state in 1896. In order to make a rough test of these two assumptions, we performed a chi-square goodness-of-fit test on the available data, assuming that it was generated by a random process.² The results from Table 2 show that significantly more lynching incidents did not occur in either of the earlier time periods and thus indicate that lynching incidents occurred randomly throughout 1896. This finding raises questions concerning Inverarity's model, but it does not validate alternate models. In order to explore the problem further, it would be necessary to present a number of alternate models and test them with time-series data.

This comment has raised questions about Inverarity's (1976) assumption that Populism was related to increases in the lynching incident rate in Louisiana in the 1890s and has questioned his use of the "boundary crisis" model. In its place, a model which defines lynching as a form of collective violence and

relates changes in this variable to political changes has been proposed. More extensive data fitted to different models will be required in order to test the various models tentatively proposed in this piece.

² In this case, the chi-square goodness-of-fit test is not designed to determine differences between sample and population results but, rather, to determine whether the observed and estimated number of lynching incidents might have been generated by a random process (Leabo, 1972:520–8). Thus, our null hypothesis, which supports the disfranchisement model or some other model, assumes that lynching incidents occur randomly throughout the year, while the alternate hypothesis, which supports the Inverarity (1976) model, assumes that they are concentrated in certain time periods. Clearly the total number of lynching incidents (19) for the year 1896 is small; however, the expected values in the individual cells are greater than five.

MECHANICAL SOLIDARITY, REPRESSIVE JUSTICE, AND LYNCHINGS IN LOUISIANA*

(COMMENT ON INVERARITY,
ASR APRIL, 1976)

Noting Erikson's indebtedness to "Durkheim's classic formulation of the relationship between repressive justice and mechanical solidarity," Inverarity (1976:262) asserts his intent to use Erikson's theory—"the disruption of solidarity (in his terms a 'boundary crisis') produces a sudden and dramatic increase in repressive justice (a 'crime wave')"—to explain lynchings in Louisiana. We applaud Inverarity's use of quantitative historical data to develop sociological theory. However, his effort is marred by both theoretical and methodological defects.

THEORETICAL DEFECTS

Mechanical Solidarity and Repressive Justice in Louisiana

We reject Inverarity's contention that lynchings in Louisiana during the Populist period constitute enactments of repressive justice in response to disruptions of mechanical solidarity. In *The Division of Labor in Society* (hereafter referred to as *Division*), Durkheim (1960:70-229, esp. 129-32, 226-9) carefully distinguished between two types of solidarity, mechanical and organic. Mechanical solidarity is based on commonalities or likenesses. Individuality is undeveloped, and individuals are interchangeable with one another. Structurally, mechanically solidary societies are undifferentiated. In contrast, organic solidarity presupposes individuality and is based on mutually complementary differences between and among individuals and on the functional interdependence of differentiated structures. There is ample reason to reject Inverarity's claim that Southern white society was mechanically solidary.

First, Inverarity (p. 268) refers to the existence during Reconstruction of the Solid South whose unity "was broken by a wave of agrarian radicalism." He suggests that for some period prior to the Civil War there was no Solid South. The Civil War helped solidify the South, and this solidarity among whites was perpetuated through Reconstruction. This

white unity was threatened, if not broken by agrarian radicalism and was restored (pp. 266, 268) as Populism was crushed. In Durkheim's theory, however, during the course of evolutionary development, mechanical solidarity gradually recedes with the growth of organic solidarity. Accompanying this change in the nature of solidarity is a change in the morphology of society from an undifferentiated "mechanical" mass to an "organic" system of differentiated and (in the "normal" instance) mutually complementary structures and functions. Durkheim did not portray societies as rapidly fluctuating in and out of mechanical status; among other things, this would require a corresponding fluctuation in the morphology of society foreign to Durkheim's theoretical perspective.

Second, Inverarity (p. 262n) asserts that "mechanical solidarity is based on similarity of individual characteristics . . . and is characterized by consensus on values, harmony . . . of interests and unity of purpose." Elsewhere, developing the idea of the Solid South, he (p. 265) refers to the "consensus on values, harmony of interests and unity of purpose among Southern whites."¹ By Inverarity's own account, the South can be seen as mechanically solidary to the extent that the features which he identifies characterize Southern white society. But do they? Inverarity's description of the South provides the answer, a description which includes "a dichotomous class structure" (p. 265), the enagement of lower class whites (at wealthier whites) that sometimes led to open rebellion against the Confederacy (p. 265n); "costs . . . borne by the poor whites" (p. 266); conflicts in interests over "railroad rate regulation, cheaper credit and higher wages" (p. 266); "the conflict between the two classes of whites" (p. 266); and Populist discussions of "open, armed rebellion" due to frustration with "legitimate means of political opposition" (p. 266). Inverarity's own description of the South provides ample basis for rejecting the claim that Southern white society was mechanically solidary. More than Durkheim's explication of mechanical solidarity, this description brings to mind the Marxian image of class conflict or the Weberian image

¹ Inverarity's portrayal of the South is problematic. He (p. 265) argued that Durkheim's concept of mechanical solidarity could be applied to the South because, "the familiar idea of the Solid South may be viewed as an instance of mechanical solidarity among Southern whites"; furthermore, "from the end of Reconstruction to the last decade of the century, the Solid South remained intact." However, in that same paragraph he also argued that "the Solid South was a social myth."

* We thank Jere Cohen for his comments on an earlier version of this paper and Carolyn J. Mullins for her editorial assistance. We also thank James Inverarity for his reactions to an earlier version of this comment. Inverarity's reactions have proved useful in our attempt to clarify the issues raised here.

of the struggle for competitive advantage between and among classes, status groups, and parties.

Durkheim, of course, asserts that mechanical solidarity persists in the organic setting to a limited degree. Given that both types are thought to be present, it is reasonable to assess the amounts and, perhaps, the relative balance between the two. In so doing, it may be tempting to view any group identified and thereby defined by a shared characteristic as mechanically solidary. The very definition itself—e.g., workers, Catholics, Southern whites—focuses attention on similarities. Clearly, however, the implicit argument that the group of individuals in question are similar on some dimension and therefore mechanically solidary is unconvincing. Obviously, further demonstration is required—a demonstration which Inverarity does not provide. For instance, he nowhere claims that Southern whites were all alike and exhibited the lack of individuality which Durkheim saw as the source of the mutual attractiveness which constitutes or leads to mechanical solidarity. Nor does Inverarity show that Southerners exhibited less individuality than that typical of individuals in organically solidary groups. Further, Inverarity nowhere asserts that Southern white society was less structurally differentiated than the modern social units which Durkheim describes as organic. Inverarity (p. 265) points simply to one commonality—the individuals in question were all white—and to their common interests *vis-à-vis* external threats (blacks, the North). However, against this must be placed his account of the severe conflicts and cleavages permeating white society, conflicts and cleavages in no way consistent with Durkheim's description of mechanically solidary groups.²

What Inverarity's description of Southern white society does bring to mind is Book Three of *Division* (Durkheim, 1960:353–95), which

describes three abnormal (pathological) forms of the division of labor. In discussing two of these forms, the anomic and the forced division of labor, Durkheim (1960:354, 355, 374) refers to "the conflict between capital and labor," the "sharp line . . . between masters and workers," and "class-wars" (compare the title, *Origins of the Class Struggle in Louisiana*, Shugg, 1939). Ironically, Inverarity's account of the South points less to the presence of mechanical than to the absence of organic solidarity.

We suggest that what Inverarity had—or, at least, should have had—in mind was something other than Durkheim's mechanical solidarity—perhaps changing levels of integration in white society.³ At least such a formulation reduces or eliminates important defects and discrepancies noted above. Specifically, this formulation (1) allows for the rapid fluctuations in level of integration described by Inverarity; (2) permits analysis of changes in the relative importance of factors that promote cleavage (e.g., class conflict) versus factors that favor a commonality of interests (e.g., external threat); (3) eliminates any implication that mechanical solidarity was predominant in Louisiana; (4) avoids any implication that Louisiana was relatively integrated as opposed to being relatively unintegrated; (5) eliminates the disparity between Inverarity's explication of mechanical solidarity and his description of the South.

Furthermore, this reformulation is consistent with both Durkheim's and Erikson's theories. Erikson's theory is not limited to instances of mechanical solidarity (see discussion below). In *Suicide* (which Inverarity does not cite), Durkheim discusses the relationship between external threats and integration. Durkheim (1951:208) argues that "great popular wars rouse collective sentiments" and thereby "cause a stronger integration of society" as people concentrate on the need to unite in the face of common danger. Durkheim (1951:160) also notes that Jews' minority status and the general hostility they confront increase the integration of Jewish society. Similarly, Inverarity (p. 265) identified blacks and the North as external threats that fostered the integration of Southern white society.

² In a personal communication, Inverarity asks: given that Durkheim treats the modern military as mechanically solidary, why cannot Southern white society in Louisiana also be treated as an instance of mechanical solidarity? We believe the reasons are clear. Durkheim (1951:234) observed that "the first quality of a soldier is" a degree "of impersonality not to be found anywhere in civilian life." Durkheim's (1951:233–9) explanation of military suicide is consistent with his observation that "of all elements constituting our modern societies, the army . . . most recalls the structure of lower societies" (p. 234). In contrast to lower societies and the military, Louisiana is a modern society, certainly as modern and organic as social structures in France and elsewhere characterized by Durkheim (1960) as (primarily) organically solidary.

³ We wish to distinguish here between Durkheim's general concept of integration or social solidarity and his types of solidarity. Integration refers to the strength of the bond between the individual and the group, while the terms "mechanical" and "organic" refer to the different forms this bond may take. In *Division*, Durkheim (1960:37–8) argues that, on the whole, integration increases as organic solidarity supersedes mechanical solidarity.

Durkheim

Erikson via Inverarity

Figure 1.

In a similar fashion, we reject Inverarity's contention that lynchings, in particular the lynching of blacks by whites, are manifestations of repressive justice. While Durkheim argues that the collective conscience and the repressive justice it engenders persist in the organic setting, lynchings do not conform to Durkheim's model. Because crime violates society's moral rules, it "shocks sentiments . . . found in all healthy consciences" (Durkheim, 1960:73). Further, violation of these sentiments invokes punishment, which Durkheim (1960:96) *summarily defines* as a "passionate reaction . . . that society exercises . . . upon *those of its members who have violated*" moral rules (*italics added*). Here, as at many other points, Durkheim emphasizes his concern for the nature and changing nature of the relationship between the individual and the group (see, e.g., Durkheim, 1960:37-8).

In the instance of lynchings, the victim is a member of an *outside* group.⁴ Blacks are *not* part of white society, nor are they lynched because of offenses committed against other blacks. Indeed, whites often remain relatively unconcerned about the offenses that blacks commit against other blacks. Rather, blacks are lynched because they have become targets of white ire. They may or may not have committed some criminal or other offense. Clearly, then, lynchings are *not* examples of repressive justice and Durkheim's argument in *Division* does not address the phenomenon Inverarity seeks to explain.⁵

⁴ Table 1 in Inverarity (p. 263) shows that 15% of the lynchings were of whites. Inverarity would have been better off assessing the applicability of Durkheim's theory to instances in which whites lynched whites, particularly for such offenses as homicide, rape, and blatant violations by whites of racial etiquette.

⁵ Simmel, of course, had much more to say about the relationship between external threats and the integration of the group than Durkheim. In *Conflict and the Web of Group Affiliation*, for example, Simmel (1964:96-8) suggests that groups sometimes may seek to maintain external threats in order to

Durkheim addresses the question of inter-group sanctions in *Moral Education*. He argues, "Whenever two populations, two groups of people having unequal cultures, come into continuous contact with one another, certain feelings develop that prompt the more cultivated group—or that which deems itself such—to do violence to the other" (Durkheim, 1961:192-3). Further, he asserts that this feeling of superiority "produces a veritable intoxication, an excessive exaltation of self, a sort of megalomania, which goes to the worst extremes," and that the violence this feeling engenders is only restrained by "moral forces which he [the one who feels superior] respects and on which he dare not encroach" (Durkheim, 1961:193). Clearly, Durkheim would apply this argument to race relations in the South rather than his model of repressive justice, in which violence is engendered by moral sentiments, not simply restrained by sentiments. Indeed, he remarks that violence engendered by feelings of superiority is common in "colonies and countries of all kinds where representatives of European civilization find themselves involved with underdeveloped peoples" (Durkheim, 1961:193).

Erikson and Durkheim as Theoretical Foundation

We may compare Erikson's theory as interpreted by Inverarity with Durkheim as follows (see Figure 1). The two models are similar in viewing reintegration as the effect of repressive justice. Beyond that, however, differences abound. Lynchings are not examples of repressive justice, so the two models address different phenomena. Similarly, the factor that elicits repressive justice differs; for Durkheim it is a moral offense, while for Inverarity it is a boundary crisis.

The two models also differ on the nature of

maintain the integration of the group. This argument seems more relevant to the relationship between Populism and lynchings than Durkheim's model of mechanical solidarity and repressive justice.

W. J. Wilson

the causal links between variables. Inverarity attempts to explain variation in the amount of repressive justice. Though Durkheim often explained variation and tested for cause-and-effect relationships by determining whether two phenomena varied systematically together (e.g., Durkheim, 1951), his model of repressive justice is not conceived in this fashion. For Durkheim, crime led to punishment, the latent function of which is to reintegrate the group. Rather than using his theory to explain variation in the rate at which repressive justice occurred, Durkheim analyzed punishment as one mechanism that explained the integration and reintegration of the group.

The attempt to use Durkheim's model to explain variation in the rate of repressive justice as a function of mechanical solidarity immediately encounters difficulties. According to Durkheim, the more powerful the collective conscience, the more it controls individual behavior. Thus, it might be argued that the more powerful the collective conscience, the less likely are moral offenses and, consequently, the lower the crime rate. However, it is also the case that the more powerful the collective conscience, the greater the number of acts that, potentially at least, might be defined as moral offenses. Thus, it might also be argued that the stronger the collective conscience, the more likely are moral offenses and the higher the rate of crime. There is a further complication. As the crime rate changes, the definition of crime also is likely to change, and that change itself affects the crime rate (Durkheim, 1964:68-9). It may be that Durkheim's recognition of these problems partly explains his failure to use his theory of the relationship between mechanical solidarity and repressive justice to explain variation in crime rates.

Inverarity (e.g., pp. 262, 272, 278) repeatedly attributes to Erikson the concept of repressive justice and sometimes (e.g., p. 272) that of mechanical solidarity. In one passage, he (p. 272) refers to "Erikson's thesis on repressive justice and *mechanical solidarity*" (italics added). However, Erikson (1966:9) stated that the argument developed in *Wayward Puritans* "should fit all kinds of human collectivity"; he did not limit his theory to instances of mechanical solidarity. Indeed, the term does not appear in his work. Thus, Inverarity's attribution of this concept to Erikson is misleading. Furthermore, this attribution is inconsistent with Inverarity's own conclusion that his test "leads to an important qualification of [Erikson's] formulation, viz., that boundary crises cause crime waves *only to the*

extent that the community is mechanically solidary" (p. 275).

Of Inverarity's three central explanatory theoretical concepts, two (mechanical solidarity and repressive justice) are found in Durkheim's work but not Erikson's, while the third (boundary crisis) appears in the latter but not the former. Clearly, Inverarity should have taken care to state the extent to which he was testing Erikson's theory, Durkheim's theory, neither, or both. Unfortunately, he often presented Erikson's theory as a direct extension of Durkheim's (see, e.g., Inverarity's characterization of *Wayward Puritans* as "the major work on Durkheim's . . . thesis concerning the relationship between repressive justice and mechanical solidarity" (p. 276). He failed to specify the relationship of, differences in, and boundaries between the work of the two men. He attributed to Erikson explicit use of two concepts found only in Durkheim. These failings, together with his erroneous claim to have tested Durkheim's theory of the relationship between mechanical solidarity and repressive justice, have produced a theoretical muddle.

METHODOLOGICAL DEFECTS

Serious methodological defects also plague Inverarity's discussion. These include the variables he uses in his MIMIC model, his failure to report the standard errors of his estimates, and the low explanatory power of his model.

Inverarity constructed his independent variables—percentage of blacks, number of blacks, urbanization, and religious homogeneity—from data found in the census of 1900 and that of 1916. The latter census occurred twenty years after the high point of Populism. Inverarity (p. 269n) implicitly acknowledges that it may be inappropriate to explain dependent variables measured at one point in time with independent variables measured at a later point in time; he argues, however, that this procedure does not undermine his empirical analysis because the intercensus correlations between the relevant variables are high. Nevertheless, this argument does not explain why data from the later period are used, given that similar data are present in the 1890 census. Furthermore, the correlations between his independent variables and the number of lynchings fluctuate considerably. For example, our data show that the correlation between urbanization *dichotomized as a dummy vari-*

able and the number of lynchings is .293 for 1890 (N.A.A.C.P., 1969; U. S. Census Office, 1892), while Inverarity (p. 270) reports a correlation of .170 with 1900 urbanization data.

A more serious problem lies in Inverarity's finding that urbanization is positively associated with mechanical solidarity. In *Division*, Durkheim (e.g., 1960:256) treated urbanization as both a cause and an indicator of organic solidarity. Thus, Inverarity finds that the greater the structural characteristics (population density and differentiation) associated with organic solidarity, the greater the mechanical solidarity. Inverarity (p. 275) suggests that this positive relationship exists *because* he coded urbanization as a dichotomous variable, and very few parishes had any urban population. As a result, he argues, the contrast is weak—between parishes that are primarily rural and parishes that contain small towns. In fact, dichotomization *obscures* a strong relationship between urbanization and lynchings. The correlation between number of lynchings and percentage living in urban areas in 1890 is .425. This figure contrasts with Inverarity's (p. 270) report for 1900 of a .170 correlation between number of lynchings and urbanization *dichotomized as a dummy variable*. Furthermore, the percentage urban in 1890 is more strongly correlated with number of lynchings than any variable Inverarity (p. 274) reports. While it is true that this correlation is inflated by an outlier (Orleans parish, which was 100% urban in 1890, experienced a number of lynchings), the relationship is undeniably positive given that nine of the twelve parishes with any urbanization in 1890 experienced lynchings between 1889 and 1898.

There are also difficulties with Inverarity's choice of dependent variables. He (p. 264) argues that voting statistics indicate the severity of the boundary crisis: the greater the Populist vote, the greater the boundary crisis. Since he also argues that boundary crises produce waves of repressive justice, the reader expects that the Populist vote as a positive indicator of boundary crisis or the Democratic vote as a negative indicator should be used to predict the prevalence of lynchings. Inverarity (p. 276), however, asserts that the parishes of Louisiana experienced only "a single boundary crisis" and, therefore, excludes political indicators as causal factors. This is untenable, given that the variation in the political crisis as indicated by voting statistics was extreme. The Fusion vote (Populists plus Republicans) in the gubernatorial election of 1896 varied from 0% in the parishes of East Carroll, Madison, Tensas and West Feliciana to over 60% in the parishes of Acadia, Lincoln, Winn, Jackson, East Baton

Rouge, St. Mary's and Assumption (New York Tribune, 1898:271). Certainly, those parishes in which there was no Populist support did not experience a boundary crisis; Inverarity, however, excludes this consideration. In fact, the correlation between degree of boundary crisis as indicated by Populist support and the number of lynchings is negative; this implies that lynchings were most numerous where the boundary crisis was the least, which contradicts Inverarity's thesis.

Inverarity uses political variables in his model as indicators of *white* "mechanical solidarity." This, too, is untenable, given that approximately half of the voters were black and, as Inverarity (p. 274n) notes, there was much fraud and coercion, particularly in counties heavily populated by blacks. Illegal tactics greatly inflated the Democratic percentage in these parishes, sometimes to nearly 100% (Webb, 1962:176–226). The result is an empirical muddle. According to the structure of Inverarity's model, the Democratic vote indicates the solidarity of whites. According to Inverarity's theoretical discussion, the Democratic vote is a negative indicator of the boundary crisis. According to historical accounts, the Democratic vote indicates the coercion of black voters. In fact, the Democratic vote may indicate all three. If this is true, however, the variable is of doubtful utility and certainly should not be used for hypothesis testing purposes.

Inverarity's measurement of "repressive justice" is also problematic. Conceived as a variable, this concept is typically operationalized as a rate. If lynchings are acts of repressive justice (we argue above that they are not), then calculation of a lynching rate should precede analysis of variations. Reed (1972:356) argues, "To relate the number of lynchings in a population to the proportion of Negroes in that population, it is necessary to calculate some sort of rate, since the absolute frequency is obviously related somehow to the population size." Inverarity, however, analyzes only the raw number of lynchings; he does not conform to the usual practice of examining the rate of lynchings, nor does he attempt to justify his focus on the raw number of lynchings.

Another difficulty is that Inverarity does not report the standard errors of the coefficients in his models. This omission makes it impossible for readers to evaluate the significance of the paths from his independent variables to mechanical solidarity. Percentage black appears to be the only important causal factor, but is it the only significant one? If it is, this fact would challenge Inverarity's argument

that he is estimating "mechanical solidarity" and, thus, alter his interpretation of his findings.

This same problem plagues Inverarity's test (p. 277) of the alternative model, which includes number of blacks as an independent variable that is hypothesized to have a direct effect on number of lynchings. The path from mechanical solidarity to number of lynchings decreases from .283 to .159 (pp. 273, 277) when number of blacks is included in the model. However, it is impossible to determine whether the path is still significant in the second model, given that it only *may* have been significant in the first. The fact that the effect is small in both models may obscure the change in level of significance.

Still another defect is the small explanatory power of Inverarity's model. As we noted, the path from mechanical solidarity to number of lynchings is weak; the amount of variation in lynchings explained by mechanical solidarity is slight. This explained variance must be assessed in the context of questionable assumptions upon which the model is based. One assumption is that the independent variables influence the number of lynchings only through mechanical solidarity. This clearly is not true for the relationship between urbanization and number of lynchings. The primary source of contemporary data on lynchings is newspaper accounts. Since newspapers are an urban medium, lynchings probably were more likely to be *reported* if they occurred in urban areas. This effect, which is unrelated to mechanical solidarity, might occur regardless of the true distribution of lynchings between urban and rural areas. The second questionable assumption—that the independent variables are measured without error—is unrealistic in most sociological models and particularly unrealistic for Inverarity's model, since his independent variables are based on data from censuses that were taken years after the Populist revolt. Finally, given the low explained variance, there is little reason to expect that these findings could be duplicated in similar analyses of other Southern states that also experienced high rates of lynchings during this same period.

CONCLUSION

Inverarity erroneously treats white society in Louisiana as an instance of mechanical solidarity and lynchings as an example of repressive justice. He produces a theoretical muddle by using concepts and causal relationships from both Durkheim and Erikson without always indicating accurately which ideas and causal relationships are from which theorist.

Often treating Erikson as an extension of Durkheim, Inverarity implies that he has tested the latter when clearly he has not. Inverarity's models suffer from various methodological defects that, together with the small amount of variance explained, make it questionable whether he has provided significant empirical support for the ideas he claims to have tested. Finally, though Inverarity claims to have tested Erikson, the latter's basic causal concept, boundary crisis, does not appear as an independent variable in Inverarity's own models. In sum, Inverarity does not show how the relationship between Populism and lynching in Louisiana can be explained in terms of boundary crisis, mechanical solidarity, and repressive justice.

TYPOLOGICAL INVALIDITY IN "GENERATION AND FAMILY EFFECTS IN VALUE SOCIALIZATION" *

(COMMENT ON BENGTON,
ASR JUNE, 1975)

Bengtson's (1975) paper was an assessment of the relative effect of generation and family upon the individual's value orientation. Since Bengtson was particularly concerned over adequate operationalization of the concept "value," he first constructed a two-dimensional value-orientation typology (adapted from that of Fallding, 1965) and performed validation procedures upon it using factor analysis. He then constructed factor scales for the purpose of operationalizing the value dimensions and used those scales as dependent variables in his analysis of the effects of generation and family. Unfortunately, Bengtson erred at the early stage of typology validation. He interpreted the factor analysis as having reproduced his typology but, in fact, only one of the two dimensions obtainable from the factor analysis corresponds to those in Bengtson's postulated typology.

The two dimensions of Bengtson's postulated typology were Expansion-Restriction and Egoistic-Collectivity; the four value types were humanism, materialism, collectivism and individualism. This typology is portrayed graphically in a two-dimensional attribute space in Figure 1. Each solid-line axis in the figure represents one of the typological dimensions (dichotomized at the origin). The circles, representing the four different value orientations as measured by clusters of items, have positions along the axes corresponding to the positions of the value orientations relative to typological dimensions (see Lazarsfeld, 1937: 126-7 regarding the characterization of types by position on coordinate axes). Note that since the value types here are inherently two-dimensional, the items measuring them are also inherently two-dimensional.

* I would like to thank Kenneth D. Bailey and anonymous ASR referees for helpful comments on earlier drafts of this paper.

Bengtson attempted to validate his typology through principal components factor analysis. A validating factor analysis would have been one which reproduced the Egoistic-Collectivity and Expansion-Restriction dimensions of the typology as factors, with the value types in the predicted positions relative to those factors. However, instead of the expected Egoistic-Collectivity and Expansion-Restriction factors, factors named "Humanism/Materialism" and "Collectivism/Individualism" appeared in Bengtson's (1975: 361) Table 1. Nor was this a mere question of labeling; Bengtson's obtained factors simply were not his postulated typology dimensions (although he termed one of them a "postulated" axis).

Part of Bengtson's problem was the use of a simple-structure factor rotation method (varimax). A simple-structure rotation (Harman, 1967) is one which minimizes the number of variables loading highly on more than one factor. It produces a set of factors such that as many variables as possible load only on single factors. The variables are then unidimensional with respect to the factors produced. The contrasting type of structure shown in Figure 1 (solid axes), where the number of variables loading highly on every factor is maximized, may be termed a complex structure. Complex-structure rotation is the appropriate final solution when the goal is to reproduce a typology of non-unidimensional constructs, as in the present case where each value orientation (and the items operationalizing it) is thought to have a non-zero position along both of two dimensions. In the case of two orthogonal axes, a complex structure and a simple structure are merely forty-five degree angle rotations of each other. If a forty-five degree angle rotation were performed on the hypothetical items in Figure 1, the dotted lines would become the axes. We would, through such a rotation, lose the typology, since the axes would no longer correspond to the Expansion-Restriction and Egoistic-Collectivity dimensions. When Bengtson performed simple-structure rotation, he perforce obtained axes passing through item clusters (whose names he therefore gave to the obtained dimensions). In addition, his factor scales operationalized dimensions corresponding to the simple-structure factors rather than typology dimensions corresponding to complex-structure factors.

If the choice of rotation method were all that was involved in the failure to reproduce the typology, Bengtson's factor solution would correspond to the forty-five degree angle rotation of his typology indicated in Figure 1 (dot-

Figure 1. Bengtson's Typology in Two-Dimensional Space (Axes I and II) and Simple-Structure Rotation (Axes I' and II'). Derived from Bengtson's Figure 1.

Table 1. Simple-Structure and Complex-Structure Loadings of the Value Items on Two Factors

Figure 2. Bengtson's Simple-Structure Rotation (Axes I' II') and the Complex-Structure Rotation (Axes I and II). (The letters correspond to item letters in Table 1.)

ted lines). But this is not the case. The position of individualism and the position of materialism in Bengtson's typology are exchanged in his factor solution.

Figure 2 (dotted-line axes) gives a graphic representation of Bengtson's factor solution. The coordinates of an item with respect to the dotted-line axes are its simple structure loadings¹ (see Table 1). The reversal of indi-

vidualism and materialism in Bengtson's solution can be seen by comparing Figure 2 (dotted-line axes) to Figure 1 (dotted-line axes). The conflict between the postulated typology and the obtained solution is even clearer in the complex-structure rotation (Figure 2, solid axes). Item coordinates are now the complex-structure loadings, which were computed from Bengtson's two-decimal simple-structure loadings² (see Table 1). A

¹ In an orthogonal two-dimensional principal components solution, each item can be expressed as a linear combination of the two factors:

$$x_i = a_{i1}F_1 + a_{i2}F_2.$$

Each item therefore can be represented in two-dimensional space as a point with coordinates (a_{i1} , a_{i2}) (see Harman, 1967).

² The matrix formula for a forty-five degree angle clockwise rotation of two factors is as follows:

$$F' = F \times \begin{pmatrix} \sqrt{2}/2 & \sqrt{2}/2 \\ -\sqrt{2}/2 & \sqrt{2}/2 \end{pmatrix}$$

comparison of Figure 2 (solid axes) with Figure 1 (solid axes) shows that rather than confirming *in toto* Bengtson's postulated typology, the factor analysis contradicts it. The items cluster approximately as intended, and Factor II does seem to have reproduced the hypothesized Egoistic-Collectivity dimension (individualism and materialism versus humanism and collectivism). However, on Factor I both materialism and collectivism are positive, while both individualism and humanism are negative. If Factor I were the postulated Expansion-Restriction dimension (see Figure 1), it would contrast humanism and materialism against collectivism and individualism, rather than humanism and individualism against collectivism and materialism as it does now. Therefore, the complex-structure Factor I is some dimension other than the postulated Expansion-Restriction dimension. However, instead of attempting to identify this new factor, which explains only about 8.4% of the variance as compared with Factor II's 17.7%, one should probably reject the two-factor solution for a single-factor solution.

Does the failure to produce the postulated Expansion-Restriction dimension mean that Fallding's (1965) typology from which Bengtson's was derived was incorrect? A reading of Fallding's article suggests, rather, that Bengtson's value items do not accurately reflect Fallding's types. Fallding's Expansion/Collectivity cell was called "membership" rather than "humanism" (see Figure 1) and entailed belonging to as much as possible. But Bengtson's items here tap only the humanistic life orientation (see Table 1). Fallding's Expansion/Egoistic cell was called "ownership" rather than "materialism" and explicitly included achievement, not only material goods and attributes as suggested by Bengtson's items. In fact, Bengtson's achievement-oriented "individualism" items belong in this cell of Fallding's typology, and not in the Restriction-Egoistic cell. The latter cell in Fallding's typology was called "interest" and related only to narrow absorbing interests such as a hobby or sport. Bengtson has no items clearly appropriate for this cell. Finally, Fallding's Restriction/Collectivity cell was called "partisanship" rather than "collectivism," and related to valuing one's own group, religious sect, etc., in opposition to other groups. Only Bengtson's "loyalty to your own" item clearly fits here, since religious participation, patriotism and friendship do not necessarily imply exclusivism but can

also be membership values. Of the items in Bengtson's two Restriction cells (individualism and collectivism), only this single item ("loyalty to your own") has clear restrictive value by Fallding's definition. It is thus not surprising that Fallding's Expansion-Restriction dimension was not obtained from the factor analysis. It has been shown that Bengtson failed to validate his own typology, but we cannot say that Fallding's typology has been invalidated; it has not been tested.

REPLY TO McCONAGHY

It is apparent that many problems in social science research can be traced to insufficient concern for construct definition prior to measurement. In particular, this can be seen in studies employing the concept "value" used so frequently in sociology with such infrequent attention given to nominal definition and empirical dimensionality. McConaghy's intent is laudable because she takes seriously what so many investigators have passed over lightly: the difficulties (perhaps the mystique) of typology construction and the use of factor analysis as a tool in construct validation.

Unfortunately, McConaghy has misinterpreted the primary goal of my analysis; worse, the criteria she employs in her critique are neither as clear-cut nor as conventionally accepted as her comment assumes. There is no "one way" to construct a useful typology, nor is there any single "best solution" in defining dimensions through factor-analytic models. Earlier methodologists (she cites Lazarsfeld, 1937, and the first edition of Harman, 1967) sought to bring some order out of chaos by asserting that particular models were *the* appropriate solution to a given problem. In contrast, more recent writings (see Heiss, 1974;

where F' is the p by 2 matrix of new factor loadings, F is the p by 2 matrix of original factor loadings, and p =number of items.

Harman, 1976:4-5) point to the several strategies and options available. They emphasize the primary criterion of "meaningful interpretation" in choosing among available logical or statistical models to best address substantively important research questions.

In my study of value socialization, the primary goal was not to validate a typology but, rather, to define dimensions which would prove useful in examining cross-generational contrast or congruence. I began with a nominal definition of values ("conceptions of desirable ends which serve as guides to action") and proceeded to operationalize the construct. I wanted the measurement design to reflect my premise that, while there are a variety of discrete values, these are patterned and organized according to superordinate cognitive categories. It is important to point out the advantages of a higher-order conceptual analysis of values, in preference to the ad hoc assessment currently in vogue (e.g., Rokeach, 1968). In defining such categories, I was drawn to an earlier suggestion (untested by survey methods) of Fallding (1965) that values might be categorized along two theoretical axes: expansion-restriction and egoistic-collectivity. Their intersection led to four cells which Fallding termed ownership, membership, interest and partisanship (labels which I felt were not the best descriptors and to which I did not subsequently refer). Questionnaire items were selected on the basis of several pretests reflecting (with varying degrees of face validity) this typology.

Data from the larger study then were subjected to principal-components factor analysis with the intent of describing the most characteristic dimensions, which I labeled humanism-materialism and collectivism-individualism. These terms were applied because they more accurately reflected the item-to-factor loading configurations, and because they had greater intuitive meaning, than Fallding's original terms. In my view, the Fallding typology is suggestive rather than definitive; my concern was to use cell types as a framework for distinguishing among sets of values in testing cross-generational hypotheses. (It should be noted that the factor analysis then was repeated for the three age-groups to be compared in the substantive analysis, with similar underlying dimensional structures found to characterize each group.)

I confess I am puzzled by McConaghy's interpretation of what a correct "typology" is and her implicit criteria for judging whether a typology is good or bad. A two-dimensional bipolar "typology" strikes me as no less

"valid" than a four-cell, or four-factor characterization. The crucial issue is utility: whether a particular set of types accurately and economically reflects data in a manner that adds meaning to cross-group comparison. Similarly, I am puzzled by her preferred-factor solution. A complex-structure rotation may be an appropriate way to validate a typology, but is certainly not useful in describing underlying dimensions with a view toward the most meaningful interpretation of data. This was my major intent in performing the analysis—to define dimensions amenable to testing hypotheses concerning within-lineage and between-generation contrasts in value orientations. Whether the dimensions employed exactly reflect what Fallding had in mind may be, as she suggests, open to question; but, in any case, this issue seems quite incidental to the analysis reported in my paper concerning cross-generational transmission of values.

ANOTHER LOOK AT MODERNITY SCALES: REANALYSIS OF THE CONVERGENT AND DISCRIMINANT VALIDITIES OF THE ARMER, KAHL, SMITH AND INKELES, AND SCHNAIBERG SCALES *

(COMMENT ON ARMER AND SCHNAIBERG, ASR JUNE, 1972)

Armer and Schnaiberg (1972) have reported that the scales designed by Smith and Inkeles,

* We are indebted to Joan Cohen and Carolyn Mullins for their editorial help.

Kahl, Schnaiberg, and Armer for measuring individual modernity are only moderate in their degree of equivalence and inadequate in their discriminant validity. Although the moderate raw intercorrelations between the four scales became considerably higher when corrected for attenuation, the authors showed even the corrected intercorrelations to be low relative to the discriminant validity coefficients relating the four modernity scales to anomia, alienation and socioeconomic status. While Armer and Schnaiberg (1972:315) stopped short of advocating the abandonment of the psychological modernity concept, they suggested that it might be a "myth." The apparent failure of the discipline's efforts to measure modernity lends credence to the charge that the concept is unmeasurable in principle. Furthermore, the concept holds little present value for empirical science if it cannot be measured on a valid instrument, and the Armer-Schnaiberg (1972) analysis apparently eliminated the most carefully developed and widely-used modernity scales available.

Fortunately, however, the need to repudiate all of the scales (with pessimistic implications for the entire modernity concept) is more apparent than real. Since the inadequacy of the scales' discriminant validities was based on a comparison to their *convergent* validities, at least part of the burden of failure can be attributed to moderate convergence. Since the degree of convergent validity reflects in part the *group* of scales selected, it is possible that one scale is greatly reducing general convergence, while the others are much higher in this regard.

Convergent Validity

Examination of the four scales tested shows that one is different in content from the others. Armer and Schnaiberg (1972) did not use Schnaiberg's (1968; 1970) full 46-item summary scale of overall modernity, but only the 24 items in the Schnaiberg emancipation scale, a subportion of the original 46. Whereas Schnaiberg's (1968) original 46 items measured six different aspects of modernity, over two-thirds (18) of the "Emancipation Scale" items deal with attitudes toward women's equality, and almost all of the rest (5) are measures of mass media exposure. One cannot consider this two-component scale sufficiently broad to encompass a many-faceted concept like modernity, which is generally agreed to contain a half-dozen or so components, including orientations toward change and custom, rationality and planning, work, and independence from one's family. These dimensions, omitted from the emancipation scale, have been found empirically, both by Kahl (1968)

and by Armer and Ycutz (1971), to be central to individual modernity.

Because emancipation is only one aspect of individual modernity and not the same as overall modernity,¹ an emancipation scale can be substituted with confidence for a modernity scale only when the two have been shown equivalent for the purposes at hand. Since the Schnaiberg emancipation scale was not designed originally to measure overall modernity, Schnaiberg (1968), in analyzing the modernity of Turkish women, proceeded cautiously before he substituted his emancipation scale for his modernity scale. He showed that emancipation was a good indicator of modernity in his Turkish sample, and that since the effects of emancipation on demographic variables were roughly equal to the effects of modernity (Schnaiberg, 1968:276), emancipation could be substituted for modernity for purposes of demographic analysis. In contrast, Armer and Schnaiberg (1972) took no such precautions. They presented no evidence that emancipation was a good indicator of modernity in their all-male Chicago sample and no evidence that emancipation and modernity correlated similarly with the Kahl, Armer, and Smith and Inkeles scales. Even more important, whereas Schnaiberg (1968:298) found emancipation to be at the core of modernity among Turkish women, there is no evidence that emancipation is at the core of modernity for Chicago males.² It is clear that emancipation is not in all cases the core of modernism. Schnaiberg (1968:314) warned that emancipation might be central to modernism only in Muslim countries, where women's exposure to modern society hinged strongly on freedom from their husbands' traditional domination and regulation. And this warning, it turns out, was quite justified: Kahl (1968) has reported that his family modernism dimension, which included husband-wife egalitarianism, was *not* a part of the core of either Brazilian or Mexican modernity, and, likewise, Armer and Youtz (1971) found that their scale of three women's equality items was not

¹ The subsets of this scale are conceptualized as measures of different aspects of modernity, *not* as separate measures of overall modernity. For a contrast, see Campbell and Fiske's (1959:87) example of the George Washington Social Intelligence Test.

² The uptown respondents were all male: whereas Schnaiberg's (1968) female respondents answered six women's equality items as behavioral reports about how much freedom their husbands allowed them, the uptown respondents only gave opinions (on these items) on what women's rights should be. Therefore, the importance of the emancipation items for the uptown respondents was in all probability less than for the Turkish respondents.

Table 1. Intercorrelations^a among Modernity Scales Uncorrected (above the Slashes) and Corrected for Attenuation Using Cronbach's Alpha (below the Slashes)^b

Modernity Scales Uptown, Wave 1	Kahl	Schnaiberg	Armer
Smith and Inkeles	.54/.77	.45/.64	.57/.95
Kahl	—	.40/.57	.64/.97
Schnaiberg	—	—	.41/.68

^a Pearson correlation coefficients are employed throughout the entire analysis.

^b All values are Armer and Schnaiberg's (1972) computations.

closely correlated with the prime dimension of Nigerian modernity. Hence, the relationship between emancipation and modernity for Chicago uptown males was, and remains an open question, and Armer and Schnaiberg (1972) were skating on thin ice in using the emancipation scale as a modernity scale. Since the emancipation scale's face validity as a modernity scale is in doubt, it would be no surprise if its convergent validity were low, indeed much lower than for the other scales.

Secondary analysis of the first wave of Armer and Schnaiberg's (1972) data shows this to be the case, for the Schnaiberg scale's convergent validity is lowest by far among the four scales tested. Wave 1 correlations of the Schnaiberg scale with the other three averaged only .41, while intercorrelations among the other three scales averaged .58 (see Table 1). After correction of all coefficients for attenuation, Wave 1 correlations of the Schnaiberg scale with the other three scales averaged .63 and intercorrelations among the other scales averaged .90. Since even after correction for attenuation the "true score" of the Schnaiberg scale explains less than 40 percent of the variance in the other scales, it does measure something different from the other three scales.

The other three scales show a much higher degree of equivalence among themselves. After correction for attenuation, the "true" score of any one (on average) accounts for about 80 percent of the variance in any other, a figure double the average for the Schnaiberg scale, and fairly high. Dropping the Schnaiberg scale and its low intercorrelations with the others raises the "convergent validity coefficients" of the three remaining scales, since these latter coefficients are simply the average correlation of each scale with the others. Table 2 presents the "convergent validity coefficients" of the Smith and Inkeles, Kahl, and Armer scales, both as computed originally by

Armer and Schnaiberg using all four scales and as recomputed *without* taking the Schnaiberg scale into account. The coefficients based on only three scales are larger in every case than those based on all four scales. Uncorrected coefficients remain moderate in size. However, this moderation is primarily due to moderate reliabilities,³ and is not a validity problem. Tests of convergent validity most appropriately examine correlations between *what is being measured* by each instrument, and such "true score" correlations are given by correcting the raw coefficients for attenuation. After correction for attenuation, three-scale convergent validity coefficients based on correlations between "true scores" (Table 2, column 2) average .90, and the .96 figure for the Armer scale approaches 1.0. Despite "prima facie differences in content" (Armer and Schnaiberg, 1972:302), the degree of equivalence in what these scales measure is quite high.

Although Armer and Schnaiberg (1972:308) found "far from perfect equivalence" when they treated all four scales as a group, one must reject the implication that *all four* scales are only moderately equivalent: the Schnaiberg emancipation scale was inappropriately included as a modernity scale and reduced average convergence. Although Campbell and Fiske (1959) note that validity is greatest where different approaches converge, they state that each independent method used to measure a trait should be "appropriate to the trait as conceptualized" (Campbell and Fiske, 1959:103).⁴ We take this to mean that an emancipation scale should not be used in a multimethod analysis of modernity scale validity; and once the Schnaiberg scale is dropped, the three scales designed to measure overall modernity show a rather high degree of equivalence.

³ It should be noted that Armer and Schnaiberg's (1972) assessments of scale reliability are probably underestimates. Heise (1969) showed that test-retest correlations are lowered by the instability of "true scores" as well as by unreliability, and Lord and Novick (1968) have stated that Cronbach's alpha is a *lower bound* for reliability, not an unbiased estimate of it. Furthermore, measured reliability could be depressed by the lack of a probability sample. According to Campbell and Fiske (1959:102), "the curtailment of the sample . . . will depress the reliability coefficients. . . ."

⁴ "Although this view will reduce the range of desirable methods," it is rarely too restrictive, for "agreement between several methods is desirable" and "convergence between two is a satisfactory minimal requirement" (Campbell and Fiske, 1959:103).

Table 2. Convergent and Discriminant Validity Coefficients for Three Modernity Scales, Wave 1, Uncorrected (above the Slashes) and Corrected for Attenuation (below the Slashes)

	Convergence		Discriminance		
	Based on 4 Scales	Based on 3 Scales	Anomia	SES	Alienation
Smith and Inkeles	.52/.79	.56/.86	-.44/-.67	.48/.81	-.49/-.86
Kahl	.53/.77	.59/.87	-.60/-.85	.34/.53	-.62/-.90
Armer	.54/.87	.61/.96	-.52/-.84	.39/.71	-.39/-.67

Discriminant Validities

Although the absolute values of the convergent validity coefficients (analyzed above) are of considerable importance, the adequacy of the scales' convergent validities also must be judged relative to their discriminant validities (see Campbell and Fiske, 1959). Since Armer and Schnaiberg (1972) found the scales' convergence lower than their correlations with anomia, socioeconomic status and alienation, they concluded that none of the scales could discriminate successfully between modernity and the latter three variables. In order to modify that judgment, we have tested whether elimination of the Schnaiberg scale increases convergence to levels higher than the discriminant validity coefficients.

Armer and Schnaiberg's (1972) comparisons of convergent and discriminant validities were repeated with the Schnaiberg scale eliminated. Three-scale convergent validity coefficients were compared to discriminant validity coefficients which correlate each scale with anomia, socioeconomic status and alienation. Even with the Schnaiberg scale eliminated, the Smith and Inkeles scale did not discriminate adequately between modernity and alienation, and the Kahl scale did not acceptably discriminate modernity from either anomia or alienation (see Table 2). However, the Armer scale discriminated adequately between modernity and all three variables, since its .61 convergent validity coefficient was greater than all three uncorrected discriminant validity coefficients (for anomia $p < .10$, and for the other two $p < .05$ in one-tailed t-tests of the type described by Walker and Lev, 1953:257). Its discriminative ability also was adequate in each case when the coefficients were corrected for attenuation ($p < .05$ in all three comparisons).⁵ Contrary to

Armer and Schnaiberg's conclusions, the Armer scale does meet Campbell and Fiske's (1959) test for discriminant validity.

While the scales are still not impressive in discriminant validity when considered together as a group, it is equally appropriate in the present case to consider the results for each scale individually⁶ for several reasons. (1) The present set of scales was not chosen according to any systematic procedure (none was reported) and, thus, do not in any sense comprise a "sample" of scales. (2) Each scale employed generates its own unique discriminant validity coefficient, and in the present case the different scales fare differently in their discriminant validity comparisons. Indeed, there are such important differences in discriminant validity between the scales that an "average" would not tell the whole story. (3) Most important, only a single valid instrument is needed to refute Armer and Schnaiberg's (1972) suggestion that the modernity concept may be too imprecise

validities *vis-à-vis* alienation. This comparison has been run utilizing the raw and corrected Wave 2 scale intercorrelations to compute three-scale convergent validity coefficients for Wave 2. However, the Wave 2 scale intercorrelations are unpublished, and the present report is limited to the reanalysis of published data.

While Althaus and Heberlein (1970) have noted that convergent validity coefficients can be elevated by methods effects, in this case discriminant validity coefficients are based on scale intercorrelations, too, and should be elevated to a similar degree. Thus, the monomethod effect for scales should give neither convergent nor discriminant coefficients a substantial advantage in these comparisons. Armer and Schnaiberg's (1972) use of a non-acquiescent subsample does not resolve this issue. It seems suspect because of the possibility of unknown biases in a select subsample. Further, their selection of a subsample non-acquiescent on the Kahl scale does not guarantee a subsample non-acquiescent on the Armer scale.

⁶ Campbell and Fiske (1959) prescribed no single procedure for interpreting tests of discriminant validity, nor have recent discussions (e.g., Althaus and Heberlein, 1970; Althaus et al., 1971) dealt with this matter.

⁵ Since alienation was measured only in the second wave of Armer and Schnaiberg's panel data, discriminant validities *vis-à-vis* alienation are from Wave 2, while convergent validities are from Wave 1. More precise is the comparison of Wave 2 convergent validity coefficients with the discriminant va-

cise to be distinguished from other, related variables.⁷ If psychological modernity were empirically indistinguishable from alienation, anomia and socioeconomic status, the Armer scale could not have distinguished them as it has: the discriminant validity of the Armer scale shows that there is a psychological modernity phenomenon that is distinct from socioeconomic status, anomia and alienation.⁸

The failure of both the Kahl scale and the Smith and Inkeles OM-6 to discriminate modernity from related phenomena indicates serious defects in these two leading scales, but the defects are readily attributable to their questionnaire designs, not to the modernity concept. The Kahl scale's problems apparently stem from the way alienation and anomia creep into many of its modernity items.⁹ "Activism" and "planning" can be denied by respondents only by acknowledging "futility" and "despair"; modern stratification and urban life can be rejected only on grounds that a few wealthy persons control everything and that the city is an unfriendly place; family ties can be embraced (on one item) only through the assertion that strangers are untrustworthy; and mass-media participation is measured as low (on one item) if political problems are rarely discussed "with your friends." Likewise, five items of the sixteen in the OM-6, while asking about certain aspects of modernity, also happen to correspond to items in Middleton's (1963) alienation scale, the measure of alienation employed by Armer and Schnaiberg (1972). In each case, non-modern responses on the OM-6 correspond to specific dimensions of alienation: few organizational memberships indicate "social estrangement"; never wanting to do anything about public issues closely resembles Middleton's (1963:973) "powerlessness"; inability to understand the thinking of a man from a different country is worded like

Middleton's (1963:973) "meaninglessness"; and both the listing of few national problems and the nonreadership of newspapers show "cultural estrangement" (Middleton, 1963:974). Although both the Kahl and Smith-Inkeles scales require respondents who wish to place themselves at a distance from modern institutions to report that they are alienated from all institutions,¹⁰ this double-barreled approach is quite unnecessary. The Armer scale's simple "I prefer to plan ahead on (few/most) matters,"¹¹ and the Smith-Inkeles items "Would you give most weight to the advice of church or government"; "What news interests you most (world/nation/village/sports/religion)"; and "Would you prefer (rural/urban) life" (not on the OM-6) show by example that items measuring modernity without asking about alienation or anomie are easy to institute. With better questions, there would seem to be no reason for these scales to discriminate poorly, since our figures for the Armer scale show that discriminance has been and can be achieved.

Conclusion

Armer and Schnaiberg's (1972) conclusions called the very concept of psychological modernity into question: if sociologists agreed only moderately on what it was and if none could distinguish it from alienation and anomie, the concept might be so imprecise that no valid measuring device could, in principle, ever be devised. The present findings serve to remove these doubts. Since three different sociologists have operationalized modernity in highly convergent ways, there is indeed a shared content to the modernity concept. Even the more serious discriminance problem is readily surmountable: sociologists can measure modernity in accord with the Campbell-

⁷ Armer and Schnaiberg (1972) seem to concur on this point. They (1972:303) state that the meaningfulness of the individual modernity concept is called into doubt if evidence of validity "is lacking for *all* scales" (emphasis added).

⁸ This conclusion is *not* subject to the qualifications suggested by Althauser and Heberlein (1970) and Althauser et al. (1971). Since only one method (questionnaire) is used for all measures, the comparisons used here to determine discriminant validity are not like any of the three types of comparison they found inconclusive.

⁹ Final determination of an item's discriminative power depends on its correlations with other modernity items and with the variables of alienation and anomie, but it is at least possible here to show which items build anomia and alienation into their very design.

¹⁰ In Chicago, a modern city, where modern culture dominates, and in the uptown area especially, which features no strong traditional communities, the rejection of modernity will certainly be more associated with alienation than in a society where tradition predominates. However, even in Chicago, it is possible to measure modernity and not alienation. The majority of the items on the short OM-6 do not confound alienation and modernity so obviously; there are 119 modernity items to choose from on Smith and Inkeles' Long Form, many of which seem alienation-free; and, of course, there is the Armer scale.

¹¹ We do not claim that *all* items and/or subscales of the Armer scale discriminate well (or as well as the scale as a whole). Armer and Schnaiberg's (1972:313) analysis of the Armer scale's subscales indicates otherwise.

Fiske canons if they are careful to choose the Armer scale. Its convergent and discriminant validity have passed and may be considered adequate. Although the Armer scale has not been validated once and for all,¹² its validity has been supported,¹³ not disconfirmed as Armer and Schnaiberg reported originally.

REPLY TO COHEN AND TILL *

Since publishing our analysis of the measurement validity of individual modernity scales, advances have been made in methods for investigating discriminant validity (Althauser 1974; Alwin 1974). While the type of data required for multitrait-multimethod analysis is unavailable in our study, it is possible nonetheless to phrase questions of convergent and discriminant validity using related techniques. Particularly important in

* We wish to thank Duane F. Alwin for helpful consultation on structural equation methods, LISREL computer program use and earlier drafts of this statement.

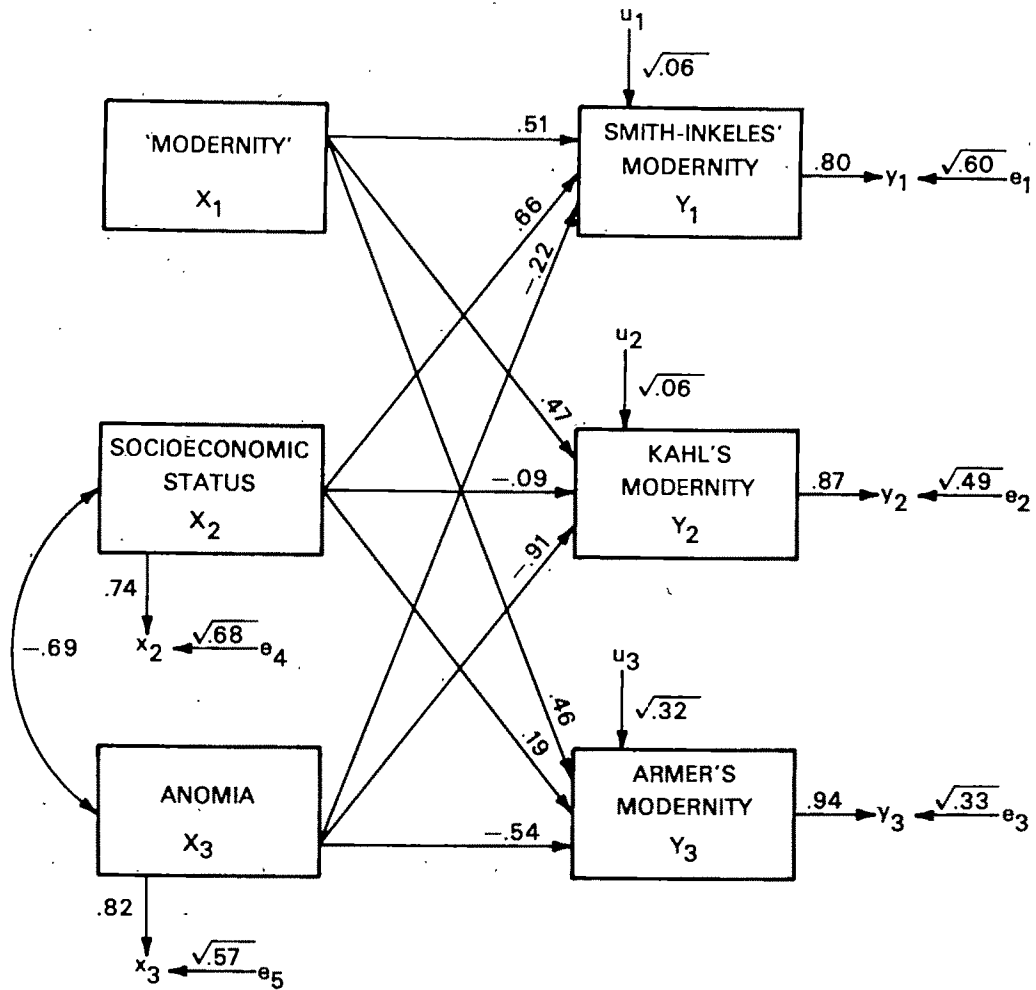

Figure 1. Path Diagram for Discriminant Validity Analysis of Modernity

this regard is the possibility of specifying and estimating a structural equation model for the correlations in our original study. Since the model implicit in our study is repeated in Cohen and Till's reanalysis, specification and testing of the model with the same data provides a more informative analysis of discriminant validity of the modernity scales, and a more constructive answer to Cohen and Till, than would a review of limitations in their evidence and inferences.

The path diagram underlying our original analysis is presented in Figure 1. The model employs three exogenous factors or traits (X_1). Two are measured constructs of socioeconomic status and anomia; the third is unobserved and is labeled "modernity." The model posits that the construct of individual modernity (X_1) is distinct and uncorrelated

at the conceptual level with the constructs of socioeconomic status (X_2) and anomia (X_3). The traits of socioeconomic status and anomia are allowed to be theoretically correlated without specifying causation between them. There are three endogenous variables (Y_1) corresponding to "true" or reliable variance in the endogenous measures (y_1) of Smith and Inkeles' "psychosocial modernity," Kahl's "modernism" and Armer's "individual modernity." Schnaiberg's modernity scale is not included in the model in order to conform to Cohen and Till's analysis even though we do not agree with their arguments for excluding it nor with their *post factum* approach to hypothesis testing.¹

¹ All of the modernity scales initially grew out of other theoretical concepts and endeavors; e.g.,

Table 1. Correlations, Means, Standard Deviations and Reliabilities for all Variables: Uptown, 1970, Wave 1 (N=156)

Variable	y_1	y_2	y_3	x_2	\bar{X}	s.d.	alpha
Inkeles-Smith's	y_1				9.308	2.617	.644
Kahl's	y_2	.540			18.217	3.636	.756
Armer's	y_3	.570	.637		33.751	3.510	.563
SES	x_2	.477	.340	.390	1.365	1.072	.540
Anomia	x_3	-.442	-.600	-.520	2.679	1.582	.672

The model states that nonrandom variation in each endogenous modernity variable (Y_i) is due to the three sources of exogenous variation (X_i) and to a unique random source of variation (u_i). The variation in observed measures of modernity (y_i) are due to "true" variation in the particular modernity variable (Y_i) and to unique unreliability or "error" variation (e_i). The structural equation framework allows one to take into account "corrections for attenuation" (in conformity with Cohen and Till's analysis) by separating the issues of random and nonrandom error and to include them as unique sources of variation.² Moreover, it allows the comparison of nonrandom variation in "modernity" scores including specific variation unique to a particular endogenous variable and variation due to the exogenous traits or factors.

The structural equations for the model in Figure 1 are as follows:

$$\begin{aligned} Y_1 &= \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + u_1 \\ Y_2 &= \beta_4 X_1 + \beta_5 X_2 + \beta_6 X_3 + u_2 \\ Y_3 &= \beta_7 X_1 + \beta_8 X_2 + \beta_9 X_3 + u_3 \end{aligned}$$

$$y_1 = Y_1 + e_1$$

$$y_2 = Y_2 + e_2$$

$$y_3 = Y_3 + e_3$$

$$x_2 = X_2 + e_4$$

$$x_3 = X_3 + e_5$$

Note that the equations for y_1 through x_3 conform to classical true score measurement models. Consistent with the diagram, the disturbance terms (u_i and e_i) are specified to be uncorrelated with the X_i , Y_i and y_i terms and with each other.³ A correlation matrix, standard deviation and reliability coefficients or the measured variables are provided in Table 1 for anyone wishing to check our results or estimate different models.

The estimated model in standard form is prescribed in Figure 1. A test for the goodness of fit of the model to the data is $\chi^2 = 0.000$ with 1 degree of freedom, $p = .998$. The largest single determinant of variation in Smith-Inkeles' modernity (Y_1) is socioeconomic status ($p = .66$) while the largest determinant of Kahl's and Armer's modernity is anomia ($p = -.91$ and $-.54$). The effect of the "modernity" factor is $p = .51$, $.47$ and $.46$, respectively.

The percentage of variance explained by valid and invalid factors is summarized in Table 2. Almost 94 percent of the total variance in Smith-Inkeles' modernity is accounted for by the three exogenous variables ($67.9 + 25.9 = 93.7$), and 72.4 percent of this is due to the invalid separate and joint effects of socioeconomic status and anomia. The same percent of total variance is explained by exogenous variables in Kahl's modernity ($71.3 + 22.4 = 93.7$), and 76.1 percent of this is due to socioeconomic status and anomia in-

Inkeles' (1960) industrial man, Kahl's (1965) achievement values, Armer's (1970) westernism, Doob's (1960) civilized man all initially grew out of research on other populations, and all have varying kinds and amounts of emphases on modernity themes. Women's rights, equalitarian marriage, family planning, etc., continue to be viewed by Inkeles and Smith (1974) and other modernity theorists as important components of individual modernity. Schnaiberg's scale cannot be selectively dismissed on any of these grounds.

² Internal consistency estimates of reliability, e.g., Kuder-Richardson KR-20 and Cronbach's alpha, are lower-bound estimates, and will be unbiased estimates of reliability only under certain conditions (see Lord and Novick, 1968:87-95). Therefore, if reliability is underestimated, any correction for attenuation will overestimate true correlations between variables (Bohrnstedt, 1970:89). In the present data, overestimation of error (e_1 — e_5) variances would produce bias in the underlying relationships. The extent of this possible bias in our analysis or in Cohen and Till's is essentially unknown.

³ In solving the set of equations we have taken random measurement error into account and have fixed the variances of e_1 through e_5 , given the knowledge of the reliabilities of the scales, and we have fixed the variances of the exogenous variables, X_1 and X_3 , as well. The model was estimated by maximum-likelihood methods under these constraints using the LISREL computer program (Jöreskog and van Thillo, 1973).

Table 2. Results of Path Analysis of Modernity Scales

Modernity Scale	% Contributions to True Variance of the Scale			% Contributions to Explained True Variance of the Scale	
	Invalidity Factors ^a	"Modernity"	Unexplained Variance	Invalidity Factors ^a	"Modernity"
Smith-Inkeles'	67.9	25.9	6.3	72.4	27.6
Kahl's	71.3	22.4	6.3	76.1	23.9
Armer's	47.0	21.5	31.5	68.6	31.4

^a Defined as socioeconomic status (X_2) and anomia (X_3) effects combined.

validity. For Armer's modernity variation on which Cohen and Till rest their defense of the concept and measurement of modernity, 68.5 percent of the variance is accounted for by the exogenous factors and more than two-thirds (68.6 percent) of this is due to socioeconomic status and anomia. Thus, while the "modernity" factor has a sizable effect on each of the three modernity measures, it accounts for only one-quarter of the total true variance in any of them; three-quarters ($67.9+6.3=74.2$) of Smith-Inkeles' true variance to 78.5 percent ($47.0+31.5$) of Armer's true variance are attributable to other nonrandom traits (X_1 and u_1).

Moreover, questions need to be raised about the conceptual identification of the X_1 exogenous factor. We have called it "modernity" simply because that is what the scale authors named the content of domain they thought they were measuring. After removing the observed socioeconomic status and anomia sources of variation in the measures, the remaining source of shared variation may be some other invalid trait or combination of traits not included as explicit exogenous factors in the model. Alienation has been identified as a probable source of variation in modernity scales in our original study and in Cohen and Till's reanalysis. Other factors with which modernity may be contaminated or confused include intelligence, social desirability or acquiescent response sets, authoritarianism, conservatism, etc. In other words, we would caution against rushing to the conclusion that factor X_2 is a new, distinct construct which can be confidently identified as "modernity" rather than one or more constructs already well-grounded in research. Further models incorporating measures of other constructs which may be producing variation in modernity scores need to be tested. The history of scale construction is strewn with measures of constructs that existed solely in the minds of their creators. The present illustration of structural equation analysis as an approach to test-

ing discriminant validity hopefully will encourage further validity analysis of "modernity" and other constructs.

In conclusion, we note that even granting Cohen and Till their principal grounds for challenging our original conclusions (i.e., dropping Schnaiberg's scale), the present analysis replicates and strengthens our initial findings. Data have been provided above for Cohen and Till and others to check our results and to re-estimate any other model which they feel better fits modernity assumptions in order to convince themselves of our original conclusion that (1972:315):

At best, the *concept* of individual modernity may be meaningful as a distinct variable, but the *measurement* of modernity has apparently been unsuccessful. At worst, the notion of individual modernity as a distinct set of orientations may be a myth, at least for some populations.⁴

1974 "Inferring validity from the multitrait-multimethod matrix: another assessment." Ch. 5 in Herbert L. Costner (ed.), *Sociological Methodology 1973-1974*. San Francisco: Jossey-Bass.

⁴ This conclusion has been ignored by many scholars who continue efforts to measure and explain modernity on the assumption that psychological modernization plays an important role in institutional and national development. However, there is evidence (Armer and Isaac, 1976) that modern attitudes tend to have little or no influence on behaviors identified by modernity theorists as relevant for development. Thus, in addition to measurement and/or conceptual problems, the theoretical and practical significance of modernity is in doubt.

tions of schools, he is developing research on the effects of educational expansion on the social status of youth.

■ **ALBERT JAMES BERGESEN** (Political Witch Hunts) is Assistant Professor of Sociology at the University of Arizona. He is presently studying status protest and anti-intellectualism in the Northeast.

■ **HOWARD S. ERLANGER** (Reform Organizations and Careers) is Assistant Professor of Sociology at the University of Wisconsin, Madison. He is continuing a study of lawyers' careers and the effects of law school on students' orientation to social reform. He is also doing a series of qualitative studies on political powerlessness and juvenile gang violence.

■ **J. CRAIG JENKINS** (Insurgency of the Powerless) is Assistant Professor of Sociology at the University of Missouri, Columbia, and is also affiliated with the Center for Policy Research. His current research includes studies on oligarchy and goal transformation in voluntary associations, the links between labor market participation, the formation of ethnic communities and ethnic stratification (using recent immigration from Mexico as a case), and agrarian class structures and rural movements (in Russia). His *Farm Workers and the Powers: Insurgency and Political Conflict (1946-1975)* will be published this year. **CHARLES PERROW** is Professor of Sociology at the State University of New York, Stony Brook, and is affiliated with the Center for Policy Research. He is currently completing a study of several social movements of the 1960s. He is also studying forms of control in organizations.

■ **BARBARA LASLETT** (Social Change and the Family) is Associate Professor of Sociology at the University of Southern California. Her work concerns historical studies of change in the family, her major current project focusing on change in the family in Los Angeles from 1850 to 1900.

■ **ROBERT F. MEIER** (The Production of Conformity) is Assistant Professor in the Program in Social Ecology at the University of California, Irvine. His research interests include processes of deviance and social control and he has a continuing interest in white-collar and corporate criminality. He is co-editor, with Gilbert Geis, of *White-Collar Crime* (Free Press, 1977). **WELDON T. JOHNSON** is Assistant Professor of Sociology at the University of Wisconsin, Madison. His interests include the social psychological dimensions of deviance and social control

and an involvement in social policy research. He is currently making a study of the legal and extra-legal conditions under which persons are detected, arrested and convicted for criminal offenses.

■ **MAYNARD L. ERICKSON** (Deterrence and Perceived Certainty of Punishment) is Professor of Sociology at the University of Arizona. He is presently making a three-year study in Southern Arizona, of Measures of Delinquency and Community Tolerance. The present paper is a result of his work in deterrence research. **JACK P. GIBBS** is Professor of Sociology at the University of Arizona. His research interests include the sociology of law, social control, deviance, and human ecology. His most recent book is *Crime, Punishment, and Deterrence* (Elsevier, 1975). **GARY F. JENSEN** is Assistant Professor of Sociology at the University of Arizona. His current research is on delinquency and religion, the social meaning of sanctions, crime among American Indians, and attitudes toward crime.

■ **JOHN W. GARTRELL** (Status, Inequality and Innovation) is Assistant Professor of Sociology at the University of Alberta. Besides continuing research in innovation and inequality in agrarian India, he is currently involved in an analysis of alienation from work using American and Canadian data sets (with Peter Archibald), and an analysis of work performance and hospitalization among a sample of schizophrenics (with Jay Turner).

■ **ROBERT L. HAMBLIN** (Arms Races) is Professor of Sociology at the University of Arizona. He is presently director of a project on Analytical Models of Conflict, which includes interaction models as exemplified in this paper as well as diffusion, collective learning, deterrence, and innovation models of conflict. The major data set being developed for analysis involves epidemics of political violence and change in Latin America. His *Behavioral Theory in Sociology* (Transaction Books) will be published soon. **MICHAEL HOUT** is Assistant Professor of Sociology at the University of Arizona. His current research interests include socioeconomic influences on fertility within the U.S. and cross-nationally. **JERRY L. L. MILLER** is Associate Professor of Sociology at the University of Arizona. He is studying internal violence in Latin America. **BRIAN L. PITCHER** is a Ph.D. candidate in the Department of Sociology at the University of Arizona. His research interests include the cross-cultural comparison of occupational hierarchies, trends in birth cohort fertility, and models of the diffusion of collective violence.

MANUSCRIPTS FOR THE ASA ROSE SOCIOLOGY SERIES

Manuscripts (100 to 300 typed pages) are solicited for publication in the *ASA Arnold and Caroline Rose Monograph Series*. The Series welcomes a variety of types of sociological work—qualitative or quantitative empirical studies, and theoretical or methodological treatises. An author should submit three copies of a manuscript for consideration to the Series Editor, Professor Robin M. Williams, Jr., Department of Sociology, Cornell University, Ithaca, New York 14853.

CHARLES C THOMAS • PUBLISHER

MUNICIPAL PUBLIC SAFETY: A Guide for the Implementation of Consolidated Police-Fire Services by Esai Berenbaum, *Department of Public Safety, Durham, North Carolina.* The entire spectrum of procedures and plans necessary for the successful consolidation of municipal police and fire services is contained in this volume. The text covers where and why this type of program is appropriate, how to plan and select a program, and what type of recruiting, training and operational techniques are most effective. The list of do's and don'ts, sample directives, job descriptions, salary schedules and organizational charts will be particularly helpful, as will the strategies for selling the program to citizens and employees. '77, 104 pp., 7 il. (4 in color), \$10.75

AN ECONOMIC ANALYSIS OF CRIME: Selected Readings edited by Lawrence J. Kaplan and Dennis Kessler, *both of the City Univ. of New York.* (25 Contributors) The readings in this book show how the vast network of organized crime affects every individual in the United States. The authors examine in detail the economics of gambling, horse racing and sports betting, the numbers game, loan-sharking, narcotics, corruption and crime in labor unions, and crime infiltration into legitimate business. Also reviewed are the questions of legalization of gambling and the financial operations of organized crime, particularly the utilization of the numbered Swiss account. '76, 432 pp., 4 il., 9 tables, cloth \$17.50, paper \$12.95

PUBLIC WELFARE SYSTEMS by J. W. LaPatra, *Univ. of California, Davis.* This book brings together in a usable, readable form the bits and pieces of work which have been done, suggests what should be done next, utilizes systems analysis to carefully define the national public welfare problem, gives a highly detailed exposition of the welfare phenomenon and identifies a long series of problems and issues which must be resolved before significant understanding of the operation of public welfare systems is achieved. '75, 232 pp., 7 il., 3 tables, \$12.50

THE DRINKING DRIVER by Barent F. Landstreet, *Virginia Alcohol Safety Action Program, Fairfax.* Foreword by Daniel W. Kriss. The problem drinker who drives has presented the courts and the law enforcement agencies with few alternatives to the application of maximum penalties. This book explains a multifaceted approach recently started by the National Highway Traffic Safety Administration to develop new and more effective methods and techniques for handling the drinker who drives. Police procedures, classification of defendants by level of drinking, and the various educational and rehabilitation programs that were developed to change driver attitude and behavior in relation to drinking and driving are just a few of the topics discussed in detail. '77, 128 pp., \$10.75

CHANGING SEXUAL VALUES AND THE FAMILY edited by G. Pirooz Sholevar, *Hahnemann Medical College and Hospital, Philadelphia.* (22 Contributors) In demonstrating how changing sexual values affect different people, this book describes such changes as viewed by sociologists, anthropologists, family therapists, psychiatrists, social workers, psychologists and students. Topics of discussion include the family system and society, sexual problems in marital therapy, incest, symbolic sex in family therapy, and techniques of family therapy. '77, 192 pp., 5 il., \$11.75

OCCUPATIONAL DISABILITY: Causes, Prediction, Prevention by Rolland A. Martin, *Univ. of Oregon Medical School, Portland.* The initial portion of this text focuses on the gross errors in the current workman's compensation system which needlessly disables injured workers. The text underscores the need for a basic change in philosophy. The principle thrust of this book, however, is the prevention of disability. Here the author puts his theories to work and offers the injured employee an alternative to permanent disability. '75, 220 pp., 16 il., 6 tables, \$14.75

DOCUMENTARY HISTORY OF AMERICAN CITIES

**Series editors: Tamara
K. Hareven, Clark University,
and Stephan Thernstrom,
Harvard University**

DETROIT

*Edited by Melvin G. Holli, University of
Chicago at Chicago Circle*

Covering the entire span of Detroit's history from its founding as a French outpost to its present position as one of the nation's largest industrial cities, this study establishes for the first time an explicit conceptual framework for viewing and understanding the city's relationship to its past and perhaps to its future. A wide variety of historical documents are included which serve to pinpoint critical periods and changes, illustrate continuities and discontinuities, and trace the main contours of the city's history. *Now available*

*Clothbound (531-05385-7) \$12.50
Paperback (531-05591-4) \$6.95*

PITTSBURGH

*Edited by Roy Lubove, University of
Pittsburgh*

A comprehensive portrait of the prototype American industrial community, this volume is the only such collection of sources for a city that was the embodiment of the American industrialization process and that pioneered in large-scale urban redevelopment after World War II.

Now available

*Clothbound (531-05384-9) \$12.50
Paperback (531-05590-6) \$5.95*

ST. LOUIS

*Edited by Selwyn K. Troen, Ben Gurion
University, and Glen E. Holt,
Washington University*

The first major contribution to St. Louis history since the turn of the century, this collection of documents and articles recreates the history of the city with particular reference to the processes by which it grew and to the problems entailed by its growth. Particular emphasis is made to economic development, demographic change, the growth of social institutions, difficulties of metropolitan governance, innovations in urban planning, the texture of urban life, and the place of the city in regional and national history.

To be published November 1977

IN SOCIOLOGY

FAMILY AND KIN IN URBAN COMMUNITIES, 1700-1930

*Edited by Tamara K. Hareven,
Clark University*

The rapidly developing field of family history, while bringing to light some far-ranging analyses, has thus far neglected research into the impact of family and demographic behavior on social change and the interaction of the family with other institutions. Now, in this volume of essays, ten outstanding scholars relate the "family process" to the "urban process," sharing a view of family organization and behavior as a process within certain historical periods and over time. Contributors are Stuart M. Blumin, Laurence A. Glasco, Sally and Clyde Griffen, Peter Dobkin Hall, Tamara K. Hareven, Dean May, John Modell, Darrett B. Rutman, and Maris A. Vinovskis. *February 1977*

THE GRASS ROOTS MIND IN AMERICA

The American Sense of Absolutes
By Conal Furay, Webster College

An exploration of the basic mental frames of reference that are common in America, those that have been and remain characteristic of the common man. The unifying theme is that despite the wrenching influences of the 20th century, the grass roots mind has retained its composure and indeed many of its principles. *April 1977*
Clothbound (531-05391-1) \$10.00
Paperback (531-05598-1) \$5.95

SEXUAL DEVIANCY IN SOCIAL CONTEXT

*Edited by Clifton D. Bryant, Virginia
Polytechnic Institute and State University*

Depending on the interpretive context, some sexual behavior may be classified as deviant when practiced in private, and tolerated as a necessary concession to the maintenance of social equilibrium when institutionalized as group or commercial enterprise. This unique collection of 20 articles examines this dichotomy in various contexts to provide a deeper awareness of the interrelated nature of certain kinds of sexual activity and other configurations of socially sanctioned behavior.

The Society of Man: Definitive Dimensions

ORGANIZATIONS: STRUCTURE AND PROCESS, 2nd Edition

Richard H. Hall — University of Minnesota

Updated sociological analysis presents contemporary data and interpretations applicable to all organizations. Includes discussion and critical evaluation of organizational theories, typologies, and structure.

Analyzes processes such as power and conflict, leadership and decision making, and communications. Examines the relationship between society and organizations — including the impact of certain organizations on the society and environmental influences on organizations. Attempts to make us aware of the critical importance of organizations, and that they must be understood before they can be controlled.

1977 384 pp. (est.) Cloth \$11.95

WORKING: CONFLICT AND CHANGE, 2nd Edition

George Ritzer — University of Maryland at College Park

Comprehensive description and discussion of the relevance of sociological theory to today's world. Covers all major occupational categories, including descriptive accounts by real workers.

Focuses on the individual in the work world and the changes he faces, career opportunities, modes of conflict resolution, problems of minority groups, and the future prospects for work in America. Special attention is given to deviant occupations, such as prostitution, and to deviant behavior within "straight" occupational groups.

1977 448 pp. (est.) Cloth \$13.95

THE EVOLUTION OF SOCIETIES

Talcott Parsons — Harvard University

A combined version of the author's two earlier volumes in the Foundations of Modern Sociology Series: *Societies*, and *The Systems of Modern Societies*.

These two earlier volumes, written as one text, were published separately to conform with the series format. They are now available as a single text for courses in Introductory Sociology, Theory, and Systems. The present edition includes a new introduction by editor Jackson Toby, as well as a glossary of Parsonian terms.

1977 304 pp. (est.) Cloth \$11.95 Paper \$6.95

RURAL SOCIETY

Irwin T. Sanders — Emeritus, Boston University

An overview of the chief characteristics of rural societies, both advanced and less developed. The major contention is that since most people of the world are still rural, the manner in which these people and their way of life is articulated into their national societies must be understood.

Students raised in an urban setting should gain a greater insight into what a farm family faces and how rural life is organized and conducted.

1977 192 pp. (est.) Cloth \$8.95 Paper \$4.95

INTRODUCTION TO SOCIAL STATISTICS

Vanderlyn R. Pine — State University of New York, New Paltz

An easy-to-understand approach to commonly used procedures in social statistics. Since research and analysis comprise an important aspect of sociology, procedures and statistics are presented to demonstrate how statistics gathered through social research may be used as (1) an analytical tool for examining quantitative data, and (2) as a practical research device.

Begins with simple statistical models from everyday life and then relates them to more complex procedures and techniques.

1977 352 pp. (est.) Cloth \$12.95

INTRODUCTION TO POPULATION: A SOCIOLOGICAL APPROACH

Judah Matras — Hebrew University, Jerusalem, Israel

Theoretical, methodological, and substantive introduction to the study of human populations, their structures, variations, and changes — and to the social structural causes, correlates, and consequences of population trends.

Summarizes world population history, recent growth trends and variations, and the meaning of the current world population explosion. Treats demographic data, measurement, and analysis; fertility, mortality, and migration; and the effects of population change on social relationships and upon economic, political, and social organizations.

1977 544 pp. (est.) Cloth \$14.95

Prentice-Hall

Understanding is the first step...

It takes many steps to find the answers to today's complex social problems. New Mosby books can bring you closer — through understanding.

A New Book! **AMERICAN SOCIAL PROBLEMS: Challenges to Existence.** By William McCord and Arline McCord. A study of major social movements, this comprehensive new text is oriented around four major themes: the search for meaning; the search for justice; the search for identity; and the search for survival. January, 1977. 303 pp. Price, \$7.95.

A New Book! **URBAN SOCIAL CONFLICT.** By Arline McCord and William McCord. Excellent for urban sociology and social change courses, this new text examines social conflict within the urban culture. Actual case studies of historical events, based on the authors' personal experiences, are included. January, 1977. 216 pp. Price, \$6.95.

A New Book! **SOCIAL INTERACTION.** By Thomas Kando, Ph.D. A true balance between sociology and psychology, as well as a consistently "humanistic" approach to the subject are the reasons you'll want this new text for your classes. Separate chapters cover: language, the self, socialization, deviance, conflict, and more! March, 1977. 366 pp., 30 illus. Price, \$9.25.

A New Book! **A SOCIOLOGY OF HEALTH.** By Andrew C. Twaddle and Richard M. Hessler; with a foreword by Talcott Parsons. Emphasizing sociology rather than health care delivery systems, this new text explores the rapid developments in the sociology of health within the past decade. You'll find contemporary insights on such topics as: disease and death; hospitals and clinics, and more! February, 1977, 368 pp., 68 illus. Price, \$8.95.

A New Book! **CURRENT PERSPECTIVES IN NURSING: Social Issues and Trends.** Edited by Michael H. Miller, Ph.D. and Beverly Flynn, R.N., Ph.D.; with 21 contributors. An exceptional supplementary text, this book consists of 15 original articles which address significant social issues now facing the nursing profession. Topics cover: ethics, research, health care delivery, organization, and education. June, 1977. Approx. 176 pp., 4 illus. About \$10.50 (C); about \$7.50 (P).

Harvest of the Palm

Ecological Change in Eastern Indonesia

James J. Fox

Centered on the intensive use of the lontar palm tree, the economy of the small islands of Roti and Savu is remarkably stable and adaptive. James Fox provides a history of this economy over several hundred years and contrasts it with larger neighboring islands.

The historical perspective adds depth to the ethnographic presentation and is vital to the anthropological analysis of social change. \$15.00

Tortillas for the Gods

A Symbolic Analysis of Zinacanteco Rituals

Evon Z. Vogt

Claude Lévi-Strauss called this study of the ancient rites and rituals of a contemporary Mayan community: "A magnificent work, a wonderful achievement which, undoubtedly, sets up a landmark in our studies." \$16.50

The !Kung of Nyae Nyae

Lorna Marshall

"This chronicle offers a lively record of a passing way of life." *Psychology Today*

Twenty-five years ago, Lorna Marshall and her family discovered and lived with a society that lived solely by hunting and foraging.

Her definitive account of this now-vanished way of life is one of the major ethnographic records of our time. \$20.00

Kalahari Hunter-Gatherers

Studies of the !Kung San and Their Neighbors

Richard B. Lee and Irven Devore, Editors

"The !Kung San project has been conducted and published as a scientific study... [with] a pervasive and genuine sensitivity, and sense of responsibility, to the people of the Kalahari. This is first-rate reading."

NEW FOR

Second Edition

CORRECTIONAL INSTITUTIONS

*Edited by Robert M. Carter, Daniel Glaser, University of Southern California;
and Leslie T. Wilkins, State University of New York, Albany*

This well balanced introduction to corrections comprises thirty-eight articles — of which twenty-seven are new to this edition — that cover the history and current status of prisons and prison systems, with particular emphasis on the problems of the

inmate. While retaining the structure of the first edition, this new edition stresses new approaches to correction, including community programs and innovative programs within prisons.

571 pages/1977/paperbound, \$7.95

Lippincott

ESSENTIAL STATISTICS FOR SOCIAL RESEARCH

Michael A. Malec, *Boston College*

Designed for students with limited mathematical background, this concise text provides enough of the basic matter of statistics to enable them to read sociological literature with some appreciation of the

function and significance of statistics. The content of this helpful book is limited to those statistics regularly used by sociologists.

235 pages/early 1977/paperbound, \$7.95

Fifth Edition

MARRIAGE AND FAMILY DEVELOPMENT

Evelyn Millis Duvall, *Family Life Consultant*

Completely rewritten and updated, this new edition includes data and findings from the latest research in the areas of marriage and family. New material includes such topics as: alternative forms of marriage; marriage contracts; sex differences and gender roles; marital options;

changing sexual attitudes and behavior; death of family members; dissolution of marriage; social change; and racial and ethnic differences. The life-cycle approach has been retained; keyed references, tables and charts amplify the text.

559 pages/March 1977/clothbound, \$12.95

OFFICIAL DEVIANCE

Readings in Malfeasance, Misfeasance, and Other Forms of Corruption

Edited by Jack D. Douglas, University of California, San Diego;

and John M. Johnson, Arizona State University

Comprehensive and up-to-date, the articles in this collection range over sociological analyses, government reports, historical and journalistic accounts, and comments by participants. Three initial articles define political corruption and show how criteria vary for defining corrupt

behavior in different times and societies. Coverage includes Watergate, CIA and FBI scandals, the NYC fiscal crisis, Kent State, Attica, and Washington lobbying. Each section has a brief introduction, and the last section offers proposed solutions to problems of official deviance.

426 pages/early 1977/paperbound, \$5.95

FAMILY STRUCTURE AND INTERACTION

A Comparative Analysis

Gary R. Lee, *Washington State University*

In this book the author demonstrates how comparative research has contributed to theory development in the sociology of the family. The focus throughout is on knowledge about family structure and behavior which has been generated, refined or ex-

tended by comparative research. Organization is topical, rather than systemic, with the objective of explanation rather than description. Controversial topics include premarital relations, sex roles, and the relationship of roles to conjugal power.

POSSIBLE TROUBLE

An Analysis of Social Problems

CLAYTON A. HARTJEN, Rutgers University

Using the "conflict-labeling" theory of deviance and society, this volume shows that the reason a person or group is labeled deviant lies in the conflict between an established and a rising group; therefore, conflict becomes the "cause," while labeling is the "consequence" of that conflict.

Cloth Text Edition, March, 1977 400 pp. \$11.95

THE I, THE ME, AND YOU

An Introduction to Social Psychology

RONALD FERNANDEZ, Central Connecticut State College

This comprehensive text approaches social psychology through symbolic interactionism; it pays specific attention to these topics: roles, reference groups, collective behavior, and the presentation of self in everyday life.

Cloth Text Edition, March, 1977 448 pp. \$11.95

THE SOCIOLOGY OF HEALTH CARE

Social, Economic and Political Perspectives

DARRYL ENOS and PAUL SULTAN

Both of Southern Illinois University

Employing an interdisciplinary approach, this comprehensive and systematic text examines the health care system in America as a whole, while presenting in-depth sociological and economic analyses of its diverse components, from doctor-patient relationships to institutional care and health care for minorities.

Cloth Text Edition, April, 1977 400 pp. \$12.00

POWER AND EQUITY

An Introduction to Stratification

WILLIAM MCCORD and ARLINE MCCORD

Both of The City College of City University of New York

Uniting social science with social philosophy, this survey of social stratification focuses on three major issues: the nature and sources of social inequality, the eternal issue of whether inequality is inevitable, and philosophical approaches concerning the nature of a just society.

Cloth Text Edition, April, 1977 336 pp. \$10.95

SOCIOLOGY FULL CIRCLE

Contemporary Readings on Society

Second Edition

Edited by WILLIAM FEIGELMAN, Nassau Community College

Now in its second edition, this imaginative anthology for introductory sociology focuses on what the sociologist does, how sociological research is actually conducted, and what issues preoccupy the mainstream of contemporary sociology. The articles included have been classroom tested for student interest and readability.

THE CRISIS OF THE ARAB INTELLECTUAL

Traditionalism or Historicism?

ABDALLAH LAROUÏ

Translated from the French by

Diarmid Cammell

Among contemporary Arab writers on social philosophy and cultural orientation Abdallah Laroui occupies a prominent position. Moreover, since few books in English consider the problems confronting many Arab intellectuals, this one—an intellectual tour de force that defines these problems in terms of history, tradition and modernity—should attract readers with an interest in the encounter between Afro-Asian and Western cultures. And because it offers strikingly sensitive and illuminating insights. Primarily a study of the foundations of culture, from a standpoint that treats politics as an essential element of culture, the book is as honest and intellectually open as it is subtle and learned.

191 pages, cloth \$12.00, paper \$3.25

Friends, Followers, and Factions

A Reader in Political Clientelism

**Edited by Steffen W. Schmidt, James
C. Scott, Carl Landé, and Laura Guasti**

Of late attention to clientelist structures has increased. In sociology this trend has found expression in the increasing use of exchange theory. In assembling this reader, the editors have crossed disciplines and subject areas. Their selections move from anthropology, to sociology, to political science; from village to nation; from theory to case study; and from continent to continent. Despite constraints of length they have retained the scope and coverage that make the volume useful to a wide readership.

INEQUALITY IN AMERICAN COMMUNITIES

By RICHARD F. CURTIS and ELTON F. JACKSON

A Volume in the QUANTITATIVE STUDIES IN SOCIAL RELATIONS Series

This book presents a multidimensional view of social rank, makes comparisons across communities and is written for both statistical and nonstatistical readers. Data are from random sample surveys of male heads of households in three pairs of communities of varying sizes in Indiana and Arizona. The

book relates social rank variables to feelings of deprivation and patterns of social participation, and uses these variables to explain differences in political conservatism, anomie, and intolerance.

1977, 376 pp., \$19.50/£13.85
ISBN: 0-12-200250-4

THE PROCESS OF STRATIFICATION

Trends and Analysis

By ROBERT M. HAUSER and DAVID L. FEATHERMAN

A Volume in the STUDIES IN POPULATION Series

Building on the concept of the socioeconomic life cycle, *The Process of Stratification* develops methods for supplementing Blau and Duncan's 1962 study of social mobility in the United States with more recent data on occupation, education, and earnings. In

the absence of a new survey specifically directed to intergenerational mobility, it uses these methods to give an updated picture of social mobility and to isolate recent trends.

1977, 384 pp., \$19.50/£13.85
ISBN: 0-12-333050-7

POPULATION

Analysis and Models

By LOUIS HENRY

Translated by Etienne van de Walle and Elise F. Jones

This book is an introduction to demography, a science which may be defined as the dynamic analysis of population structure and size. In addition to covering the conventional substance of demography—source materials, methods of description, nuptiality, fertility, family formation and mortality—the author deals at length with topics usually neglected in demographic textbooks, such as the treatment of migration in particular, and its effective

integration with population structure. The second half of the work is devoted to models, combining a lucid explanation of the nature and point of mathematical models in demography with practical demonstration of their use.

1976, 302 pp., \$19.50 ISBN: 0-12-341250-1
Academic Press Sales Territory: United States and Latin America

A DECADE OF FEDERAL ANTIPOVERTY PROGRAMS

Achievements, Failures, and Lessons

Edited by ROBERT H. HAVEMAN

A Volume in the INSTITUTE FOR RESEARCH ON POVERTY-
POVERTY POLICY ANALYSIS Series

Prepared for a major conference held in February 1975 under the aegis of the Institute for Research on Poverty, the eight papers in this volume review the policies of the first decade of the War on Poverty. Specific program areas are: income maintenance by Laurence Lynn, health care by Karen Davis, community action by David Greenstone and Paul Peterson, legal services by Ellen Jane Hollingsworth, equal opportunity in housing and employment by Phyllis Wallace, and edu-

cation and training by Henry Levin. Lawrence Friedman explores the forces that stimulated the War on Poverty; and Robert Haveman's overview essay treats the likely nature of the next decade of social policy. Two commentaries from conference discussants follow each paper.

CONDENSED EDITION

The Methods and Materials of Demography

By HENRY S. SHRYOCK and JACOB S. SIEGEL

Condensed Edition edited by EDWARD G. STOCKWELL

A Volume in the STUDIES IN POPULATION Series

The Condensed Edition of *The Methods and Materials of Demography* elucidates the sources, limitations, underlying definitions, and bases of classification of demographic data, as well as the techniques and methods that have been developed for summarizing and analyzing them. Topics covered include formal demography and the study of many social and economic characteristics of the population.

The derivation of the demographic measures described is illustrated in step-by-step examples using actual statistics, drawn from a wide range of geographic areas, both in the United States and abroad. Considerable emphasis is placed on the kinds of data available for statistically underdeveloped areas, as well as on the special methods applicable to these areas. At the same time, the materials of the United States are covered in great detail, especially with respect to sources, definitions, and historical developments.

1976, 576 pp., \$16.50/£11.75 ISBN: 0-12-641150-6

Evaluating Social Programs

Theory, Practice, and Politics

Edited by PETER H. ROSSI and WALTER WILLIAMS

A Volume in the QUANTITATIVE STUDIES IN SOCIAL RELATIONS Series

Evaluating Social Programs addresses itself to three questions which are crucial to effective social action (and hence to the lives of those whom social programs are designed to improve): 1. Why has so little high quality evaluative research been done? 2. What problems are involved in developing more evaluative research and using its results in policy making? 3. What should government and social scientists do to foster soundly conceived and executed evaluative research?

The essays in this text—all of them written by leading social scientists—throw new light on each of these questions, but special attention is devoted to the first: i.e., the conceptual, methodological, bureaucratic, political, and organizational factors that hinder sound evaluation. The essays deal not only with the complexities associated with each factor, but also with the many ways in which the factors become intertwined in practice.

Understanding the shifting sexual and family tensions in our culture.

One of America's best-known social critics, the author of the bestselling *Pursuit of Loneliness*, discusses the two related and crucial crises facing our culture today: the profound changes in sex roles and in the Western-style family.

"Philip Slater is absolutely marvelous. His writings are inevitably loaded with insight, sensitivity, ingenuity. No one plays with ideas and comes up with the sorts of profound observations as he does. No one understands this country, its working and its failures better than he

does. Reading Slater is fun; it's an education, an enlightening experience, a supreme pleasure." —THOMAS COTTLE

author of *Time's Children*

"It contains many exciting insights into the human condition which are expressed in a simple and delightful style of writing."

—ALEXANDER LOWEN, author
Bioenergetics

"Penetrating arguments from an astute observer."

THE GROWTH OF CRIME

The International Experience

Sir Leon Radzinowicz and Joan King

The world today is in the grip of a massive and seemingly irreversible crime wave. That is the disturbing but fully documented conclusion of this important book by Sir Leon Radzinowicz, who is generally recognized as the world's leading criminologist, and co-author Joan King.

THE GROWTH OF CRIME is the first authoritative attempt to take an international, comparative look at every aspect of crime and law enforcement—from police and sentencing through prison, punishment and rehabilitation—in order to see what has been tried, what works and what does not. The authors conclude that nowhere does the system work well, but warn that many proposed reforms have already been tried somewhere and found wanting.

"Invaluable . . . provides us with the perspective needed to understand better the apparent increase in crime throughout much of the world."

—MARVIN E. WOLFGANG, University of Pennsylvania.

The Dual Vision

Alfred Schutz and the Myth of Phenomenological Social Science

ROBERT A. GORMAN

Hampton Institute, Virginia

A systematic exploration and indictment of the movement to re-define the social sciences through a subject-oriented phenomenological approach, the book focuses on a critical examination of the life-work of Alfred Schutz. Dr Gorman shows why Schutz and his followers fail in their attempt to 'humanize' empirical social science, and argues that the problems they encounter are due to their desire to achieve an artificial unity of subjectivity and objectivity – their 'dual vision'.

International Library of Sociology \$8.75

Origin and Significance of the Frankfurt School

A Marxist Perspective

PHIL SLATER

The City University, London

Examines the formative and most radical years of the Frankfurt School, during the 1930s. Phil Slater concentrates on the contributions made to a 'critical theory of society' by various thinkers, including Herbert Marcuse, Max Horkheimer, Erich Fromm and Theodor W. Adorno.

International Library of Sociology \$13.75

Talcott Parsons and the Social Image of Man

KEN MENZIES

University of Guelph, Ontario

This lucid account of Talcott Parsons's work looks critically but sympathetically at his basic concepts and their interrelation. Two major strands which run throughout Parson's work are examined separately – his social action theory, and his systems theory (structural-functionalism).

The Social Context of Violent Behaviour

A Social Anthropological Study in an Israeli Immigrant Town

EMANUEL MARX

Tel-Aviv University

Foreword by the late Professor Max Gluckman

Based on the detailed investigation of incidents of violent behaviour among Moroccan immigrants in a new town in Israel, this study examines some of the most common kinds of personal violence, from wife-beating to shop-wrecking.

\$8.25

Social Class, the Nominal Group and Verbal Strategies

PETER HAWKINS

Victoria University of Wellington,

New Zealand

Foreword by Professor Basil Bernstein

The author undertook a grammatical analysis of the speech of a large sample of five-year-old children, and reports here on the results of his research. He is concerned in particular to discuss the relationship between the use of certain grammatical structures and such factors as social class, IQ and sex.

Primary Socialization, Language and Education Series \$20.25

Code In Context

DIANA S. ADLAM

Thames Polytechnic, London

With the assistance of Geoffrey

Turner and Lesley Lineker

Foreword by Professor Basil Bernstein

Contains theoretical and empirical investigations of Basil Bernstein's widely influential work on children's sociolinguistic codes, stressing his present emphasis on the semantic orientations which different children may be acquiring, and discussing his ideas in relation to work being done elsewhere, particularly in the United States.

Primary Socialization, Language and Education Series \$14.50

The new

SOCIOLOGY TEXTS FOR 1977

SOCIOLOGY: An Introduction

Reece McGee
Purdue University
and others

Following two main themes—
social organization and the
personal usefulness of
sociology—

Reece McGee and
nineteen other sociologists,
who consistently teach the
introductory course, have
written a new compre-
hensive introductory
sociology program
consisting of a main text,
Student Study Guide, and
Instructor's Manual.

Covering all the traditional
areas of study, *Sociology: An
Introduction* gives in-depth
treatment to basic concepts,
theoretical issues, vocabu-
lary and classic studies.

*Sociology: An Intro-
duction*. It has every
component necessary to
teach a complete course
successfully.

KEY FEATURES IN THIS OUTSTANDING NEW TEXT:

- Chapter-opening vignettes that both stimulate interest and immediately illustrate to the student the relationship between sociological concepts and real-life occurrences
- Generous illustrations including boxed materials, charts, graphs, cartoons, and photographs, which will enhance the student's understanding and awareness of sociological concepts
- Chapter outlines and summaries to assist students in organizing the material
- A new, proven pedagogical device—the "running glossary"
- Chapter Two (Scientific Method In Sociological Research) is a simply written, essentially non-quantitative introduction to methods which reviewers have acclaimed as one of the text's most outstanding features. The logic and research procedures are

emphasized, rather than
the computational
aspects

- A complete teaching-learning package
 - An Instructor's Manual with film guide
 - A 3x5 Card File Test Bank
 - A Study Guide containing chapter summaries, chapter outlines, key word check lists, self-tests, and suggestions for further study, term paper and research projects

ISBN: 0-03-089704-1/650 pages

FROM HOLT

SOCIOLOGY AND SOCIAL ISSUES,

Second Edition

Ronald A. Hardert,
Erdwin H. Pfuhl,
William A. Anderson
Arizona State University

Howard A. Parker
University of Hartford

Using a social problems orientation, this introductory text develops issues pertinent to the sociology of the mid-70's. Its emphasis is on social interaction and change with attention to the problems of women, blacks, native and Mexican-Americans, poor Appalachian whites, and other minorities. Topics of special interest include communes vs. competition, technology, sexism and society, and labeling theory. A new concluding chapter on social change has been added to this edition. Instructor's Manual ISBN: 0-03-089897-8/352 pages

SOCIAL PROBLEMS,

Second Edition

Frank Scarpitti
University of Delaware

This new edition of a successful text has been completely reorganized for a more logical presentation. Fifteen significant problems are analyzed from the perspectives of value conflict, social disorganization, and deviance. Two new chapters discuss the sociology of social problems and future solutions. *New Features* include chapter summaries, a glossary and a

unique set of cassette interviews with well-known personalities on current issues. Instructor's Manual and 3 x 5 Card File Test Bank.

ISBN: 0-03-018366-9/600 pages

SURVIVAL IN MARRIAGE:

Introduction to Family Interaction, Conflicts, and Alternatives,

Second Edition

Gail Putney Fullerton
San Jose State University

Marriage and the family, marital and sex roles are examined from both historical and contemporary perspectives. The text deals with change-making influences such as the urban environment, divorce laws and communes. New chapters treat sexual intercourse and post-marital roles. More material is present on the economic factors of marriage than any other text. Instructor's Manual.

ISBN: 0-03-089748-3/592 pages

HOW TO RUN ANY ORGANIZATION:

A Manual Of Practical Sociology

Theodore Caplow
University of Virginia

How to avoid common pitfalls and achieve success in five fundamental areas—authority,

communication, productivity, morale, and change. Based on extensive sociological research, this supplementary text emphasizes practical application as it covers the management of all types of organizations—from summer camps to hospitals to large corporations.

ISBN: 0-03-014886-3/288 pages

SEXUAL SCRIPTS:

Social Construction of Female Sexuality

Judith Long Laws
Cornell University

Pepper Schwartz
University of Washington

These original essays present a feminist analysis of female sexuality in relation to the social environment. Written by women who are experts in their fields, the essays provide an integrated view of how female sexuality is shaped by our culture. Discussion includes sexual identity, sexual socialization, body processes and cultural proscriptions, and judicial reaction to female sexuality.

**SOCIOLOGY: CHANGE
AND CONTINUITY**

Carol A. B. Warren,
University of Southern California

Written for introductory sociology students, this compelling text focuses on those areas of social life which are continuous over time, and on those which represent change: *social problems and transition.*

**PARENTS IN MODERN
AMERICA, Third Edition**

(paperbound)

E. E. LeMasters, *University of Wisconsin*

Updated to include social change of the 1970's in almost every chapter. Examines the American mother and father, parents, mass media, and the youth peer group, among others.

**CRIMINOLOGY: POWER,
CRIME, AND CRIMINAL LAW**

John F. Galliher and James L. McCartney,
both of the *University of Missouri*

An analysis of the criminal justice system that discusses criminal behavior mainly as a political and cultural product created by powerful interest groups and their representatives: *legislators, police, and judges.*

**SOCIOLOGICAL RESEARCH:
PHILOSOPHY AND METHODS**

Henry L. Manheim, *Arizona State University*

Presents a unique combination of the philosophical assumptions underlying any research activity, and the practical methods of doing research in the social sciences.

Examination copies for adoption consideration available on request. Please indicate course title and text presently used.

THE SOCIOLOGY OF WOMEN'S ECONOMIC ROLE IN THE FAMILY*

VALERIE KINCADE OPPENHEIMER

University of California, Los Angeles

American Sociological Review 1977, Vol. 42 (June):387-406

This paper examines Parsons' argument that wives' socioeconomic contributions to their families are, of necessity, minor in our society and that to the extent a wife does work, family stability requires that it be at a lower occupational level than her husband's. A reassessment of the theoretical considerations involved indicates that Parsons' preoccupation with the potentiality for status competition and conflict between working spouses has led to a distorted view of the problem of status consistency within the family. The argument presented here is that, if the wife is to work, it is important that her occupation reflect favorably on the family's socioeconomic position and this need for status maintenance, if not improvement, offsets the presumed need for her occupation not to be status threatening. In addition, it is suggested that Parsons overestimated the amount of disruptive competition which would necessarily occur if both the husband and wife worked. Some empirical evidence is presented to support this alternative view of women's socioeconomic role in the family.

In spite of the rapidly increasing labor-force involvement of married women since the early 1940s, sociologists have usually assumed women's socioeconomic role in the family to be minimal. This has been particularly characteristic of stratification research which traditionally has concerned itself with measuring and studying the socioeconomic status of males alone. This approach was based on the long-accepted theory that an adult female's socioeconomic status is determined by her husband, and that a woman's major role is that of wife and mother while it is only her husband who has an important occupational role. Occupation, in turn, generally has been considered the major source of socioeconomic status in our society. Hence, by ascertaining the occupational status of a man one

could, at the same time, determine the socioeconomic status of his wife (Parsons, 1943; Centers, 1949; Turner, 1964).¹ Thus, as long as a wife's economic role in the family could be considered negligible, the conceptualization and measurement of socioeconomic status—whether of individuals or family units—had considerable theoretical simplicity.

In recent years, however, there has been a rapidly blossoming interest among stratification researchers in measuring the socioeconomic status and social mobility of women. This is partly because of a resurgence of interest in marriage as a status attainment process and partly because of a growing recognition of the status implications of the enormous increases in married women's labor-force participation. One group of researchers has been primarily interested in mobility, following very much in the footsteps of such classic studies as Blau and Duncan's *The American Occupational Structure* (1967). How-

*This is a revised version of a paper presented at the 1974 annual meetings of the American Sociological Association, Montreal, Canada, and is based on research funded by the Russell Sage Foundation. The author wishes to express her appreciation for the extremely helpful comments on earlier drafts of this paper by Joan Huber, Karen Oppenheim Mason, David Heer and Judith Blake, as well as the anonymous referees.

¹ For a critical discussion of these traditional views of women's socioeconomic role, see Day, 1961; Watson and Barth, 1964; Ackers, 1973; Haug, 1973; Ritter and Hargens, 1975.

ever, instead of just analyzing samples of males, they have focused increasingly on women as well (Chase, 1975; Glenn et al., 1974; DeJong et al., 1971; Treiman and Terrell, 1975; Tyree and Treas, 1974). Their concern has been primarily to measure intergenerational mobility of women, typically taking father's occupation as the origin point. For the destination status, two alternatives generally have been chosen. One is the woman's (usually a wife's) own occupation for a measure of social mobility via occupational achievement (Tyree and Treas, 1974; DeJong et al., 1971; Treiman and Terrill, 1975). The alternative destination status often selected is the socioeconomic status of the woman's husband, the goal here being to study marital mobility (Tyree and Treas, 1974; Glenn et al., 1974; Chase, 1975).

Unfortunately, by opting for only one of these alternatives, such studies present a unidimensional view of socioeconomic status. They look at either the wife's own occupational status *or* her status as derived from her husband, but not both simultaneously. Hence, to the extent a wife's (or a husband's, for that matter) *overall* socioeconomic status is partly a function of her (his) labor-force and occupational status and partly a function of her husband's (his wife's) occupational status, these approaches cannot give us an overall measure of the socioeconomic status of wives, their husbands, or the family as a unit. Nor can they enlighten us on the relationship between the occupational statuses of husbands and wives. They fail in this because, in effect, the rules of the game have changed. Measuring the occupational status of one individual in a family now frequently provides nothing more than a partial indicator of either the *family's* socioeconomic status or that of the individual in question because socioeconomic status will be influenced by the occupational achievements of other members of the family as well—most notably, the spouse for adult married people. This is not to say that these studies necessarily claim that they are measuring overall socioeconomic status and have failed to live up to this claim. What is meant is simply that, whether or not they have tried to construct an overall

measure, they have not succeeded in doing so. Instead, we have a rather fragmented view of the socioeconomic status of both individuals and families. As a result, while the indices used by previous studies to measure socioeconomic status (such as the Duncan Socioeconomic Index) may serve some of the purposes of current mobility analyses, they are becoming less relevant as general measures of socioeconomic status which can be used in a variety of sociological studies in other substantive areas of research.

While current mobility investigators have not attempted to create a composite measure of socioeconomic status for either individuals or family units, a number of other investigators have dealt more explicitly with this problem—arguing that the wife's as well as the husband's occupational status should be considered jointly in determining the socioeconomic status of an individual or family. Day (1961) argued at length for a more extensive consideration of the status impact of the working wife and Barth and Watson (1967) did some exploratory work on the effect of wives' working on their families' life-styles. More recently Rossi et al. (1974) have been involved in research indicating that the wife's socioeconomic characteristics, as well as the husband's, play an important (though unequal) role in the social standing of the household as a whole (see Sampson and Rossi, 1975; Haug, 1973; Ritter and Hargens, 1975).

These investigators have been concerned primarily with the issue of whether wives, as well as husbands, have an impact on the wife's or family's socioeconomic status. They have not been overly interested in the nature of the relationship between the wife's occupational characteristics and those of her husband. However, this is an important question in its own right because of the strong possibility that there exists a causal relationship between the socioeconomic contribution of the wife and her husband's socioeconomic characteristics. Most research on female labor-force participation, for example, has shown that whether or not a wife works—hence, whether or not she has an occupational status

to measure—is related to such socioeconomic characteristics of the husband as his income (Cain, 1966; Bowen and Finegan, 1969; Sweet, 1973; Mincer, 1962). The further question is whether the socioeconomic level of her occupation may not also be influenced by her husband's socioeconomic characteristics. It is this issue of the causal relationship between the wife's socioeconomic contribution to the family and her husband's socioeconomic characteristics that provides the primary focus of this paper. The major goal will be to examine critically certain traditional theories about sex roles and to try to modify them so as to achieve a theoretical approach more in keeping with the emerging realities of the socioeconomic behavior and characteristics of men and women.

Although a number of sociologists have discussed the nature of women's socioeconomic role in the family, one of the most influential theories dealing with this issue is found in the writings of Parsons. Because Parsons' work has been so influential and is one of the more carefully elaborated statements on the topic, the discussion of sociologically "traditional" views of women's economic and family roles will be limited to a critical examination of some aspects of the Parsonian approach. Parsons' work is of particular interest here because his theory about women's economic role in the family is developed mainly in terms of certain hypotheses regarding the causal relationship between husbands' and wives' occupational behavior.

Parsons' discussion of the nature and determinants of women's socioeconomic role in the family has a number of facets. Particularly important is his argument that sex-role segregation is a functional necessity for marital stability in our society (Parsons, 1949:193). As a consequence, Parsons (1949:195) argued, most women must be relatively excluded from the occupational system, "at least in a status-determinant sense." This is so, Parsons maintained, because the marriage relationship is structurally unsupported in an urban industrial society and, as such, is fragile and easily disrupted without protective mechanisms. The major mecha-

nism preventing disruptive competition between husband and wife is sex-role segregation, where the dominant male role is the occupational role and the dominant female role is that of housewife and mother (Parsons, 1949:193). Since the major source of socioeconomic status is occupation in our society, a married woman working raises the possibility of disruptive competition between the spouses. If marital stability is to be maintained, married women must either avoid work or work at an occupation which is not status competitive—for example, it must be at a "job" rather than a "career" and "ordinarily does not produce a comparable proportion of the family income" (Parsons, 1949:193ff.). As a consequence, wives will make an insignificant impact on the family's socioeconomic status (Parsons, 1954a:80).

There are two aspects of Parsons' theory which are of major interest here. First, it is important to scrutinize quite carefully his notion of the role of status consistency in affecting women's economic role in the family. This paper will argue, with Parsons, that status consistency—or at least a liberalized version of the concept which will be called "status compatibility"—is important in maintaining family solidarity. However, Parsons deals with the deleterious effects of competition, while the argument presented here will emphasize the role of status maintenance and status enhancement as the crucial factor which encourages employment of wives under certain conditions and discourages it under others. There is also the question of whether competition is as important a problem in the two-worker family as Parsons hypothesized. This paper will argue that Parsons overestimated the competitive difficulties inherent in such a situation and failed to consider a number of factors which could prevent or neutralize the competitive conflicts which he saw as inevitable.

Although a number of Parsons' views regarding sex roles are under question here, there are two which are not particularly at issue. The first is the assumption that direct competition is probably damaging to intimate relationships. Second, Par-

sons has argued that a long-standing norm in our society is that the husband is the major provider and status determiner in the family. I will proceed under the conservative assumption that these are true.

STATUS COMPATIBILITY AND THE PROBLEMS OF STATUS MAINTENANCE

One reason that Parsons gave for the necessity of sex-role segregation was that conjugal solidarity is inconsistent with drawing class distinctions between husband and wife. If such distinctions did arise, he argued, disruptive competition would occur. It is clear that Parsons' position is based mainly on his assessment of how the internal dynamics of the conjugal family operate. However, the problem might be more profitably approached from a somewhat broader perspective—that is, by focusing, in addition, on the family as a basic unit in the stratification system of the society.² By viewing families within the context of the larger stratification system and, hence, in competition with other families for status, then it is clear that one problem families, as solidary units, face is that of status maintenance or improvement. This perspective on the family is thoroughly consistent with Parsons' own views. He emphasizes the universalistic and achievement orientation (i.e., competitive nature) of our occupational system as well as seeing the family as a basic unit of stratification, one which is inevitably concerned with its status position relative to other families in the society (Parsons, 1954a:77ff., 85ff.; 1954b: 422ff.).

Unfortunately, Parsons did not really follow through on this picture of the family in analyzing the determinants of women's economic role. However, looking at the family as a solidary unit concerned with status maintenance and enhancement should indicate how these larger status concerns can promote rather than minimize wives' economic role while, at the same time, structuring the nature of that

role. It is true that, to some extent, Parsons recognized the importance of economic pressures promoting wives' labor-force participation in his assessment of the more important economic role of women among the "low ranges of occupational and income status" although he also thought a high price was paid for this in marital instability (Parsons, 1949:194). However, economic pressures for the wife to work are not limited to lower-class families but are operating throughout the society and probably increasing over time (Oppenheimer 1974; 1976). Moreover, opportunities for wives to work rose rapidly in the postwar period, encouraging a positive response on the part of wives to a desire for a higher family income (Oppenheimer, 1970; 1973). And the more wives who respond to such economic pressures and economic opportunities—middle- as well as working-class—the greater the relative socioeconomic disadvantage of families without working wives (Oppenheimer, 1976).

Emphasizing the importance of the family as a unit in the larger stratification system leads to a somewhat different interpretation than Parsons' of the role of status consistency. Parsons argued that it is essential to have status consistency within the family because status discrepancies would lead to disruptive competition. Although status consistency is important, there are more compelling reasons for its importance than the possibility of disruptive competition. That is, status consistency is important not so much because highly divergent statuses would lead to competition but because they would threaten the status position of the family as a whole as well as the statuses of individual members of the family. Parsons does not take this possibility into consideration because, first, he neglected to keep in mind the status-maintenance problems of the family and, second, he developed only a one-sided view of the negative consequences of status inconsistency. Thus Parsons' theory implies that the only labor-force involvement of wives compatible with family stability is one where the wife has a lower-level job than her husband—a job which, as a consequence, somehow does not count. Pre-

² One need not think of a single stratification system in the society but of a multiplicity of systems, i.e., any particular family in competition for status with a number of families, not with every other family in the society.

sumably, if she should have a job which is at a higher socioeconomic level, such a discrepancy would "put an intolerable strain on the imperative of class equality" and, hence, on the marriage (Parsons, 1949:195). However, one might just as well argue that if there are negative effects stemming from a wife having a *higher* occupational status than her husband, there will also be negative effects if she has a much *lower* status. Thus, Parsons is not consistent in the development of his basic argument—the importance of status homogeneity within the family. His theory comes perilously close to an argument for the functional necessity *not* of equivalent evaluation within the family but of male superiority.

It is possible to start with Parsons' original idea—the importance of status homogeneity—and develop it in a more relaxed and evenhanded fashion, without any recourse to functional imperatives. First, it seems reasonable to assume that the social statuses of closely associated individuals (such as family members) tend to rub off on each other. In other words, all members of a family tend to share at least some of the benefits and liabilities of their individual status sets. As a result, there is a strain toward status consistency within social groups such as the family; if one or more of the statuses of one member of the family are much lower than the statuses of the other members it reflects poorly on the others. In addition, the individual with the much lower status finds himself at a disadvantage *vis-à-vis* the others and, perhaps, at a disadvantage relative to the other statuses in his own status set. As far as the internal social system of the family is concerned, this may result in a loss of prestige, power or affection. Therefore, a strain toward status consistency is often to the advantage of all concerned. As a consequence, where a publicly-known status of one member of the family group is much below that of other members, certain social mechanisms should come into play to deal with the disadvantages resulting from such a marked status inconsistency.

(1) The offending status is given up, if possible, or, if only contemplated, its attainment is not pursued. One example

might be the case in which an alcoholic wife or husband reforms.

(2) The negative effect of the highly discrepant status is somehow neutralized, especially when there are some benefits from the status as well as some potential liabilities. One way neutralization may be achieved is by a consensus on the temporary nature of the status. For example, the status may be considered appropriate for one stage of the individual's life cycle but not for another. Thus, a man of high socioeconomic status may have no qualms if his son works as a construction worker during the summer while on vacation from school, but the father's feelings will be very different if the son proposes to spend his life doing cement work.

(3) The relationship with the family member who has the much lower status is severed. Thus, at one time, young women who became pregnant with no wedding in sight so compromised their own status and that of their families that many ran the risk of being disowned.

(4) The family opts out of the usual evaluative system. With respect to the social stratification system, for example, they may decide to recognize no hierarchy of occupational statuses at all, and the highly discrepant status is definitionally eliminated. However, as long as any evaluative systems are in force, the dilemma remains.

How are such mechanisms likely to operate in marriages where both spouses are not only working or contemplating employment but where the possibility of highly divergent occupational statuses also arises? In such cases, the operation of these mechanisms has been strongly influenced by the relatively long-standing norm in our society that the man be the major provider and status determiner. To the extent such a norm is flourishing, it will affect which mechanisms come into play because a different meaning will necessarily be attached to the status inconsistency depending on whether the wife's or husband's status is the much lower one.

Take the case where the wife has achieved a much higher occupational status than her husband. Because the normative expectation is that the husband

should be the status-determiner for the family, this limits the kinds of mechanisms which will deal with this type of status inconsistency. For example, he does not have the social option of eliminating the status discrepancy by quitting work. While the negative effects of the discrepancy may be neutralized for a time by interpreting his much lower status as temporary for some socially acceptable reason, he remains at a disadvantage unless he can soon achieve considerable upward mobility. On the one hand, the wife does have the option of eliminating the status discrepancy by quitting work and this may be one resolution of the conflict, probably at some psychic costs to her. On the other hand, she may change husbands—or at least do without the lower-status husband—rather than relinquish a relatively rewarding occupational career for a socioeconomic status that is lower than she could achieve herself. Of course, what happens in any particular case will depend on other aspects of the marriage as well. However, given current family norms, this type of status discrepancy is likely to create severe strains in the marriage relationship and will increase the probability of separation and divorce as the means of dealing with the problem.

Most married women in our society have had socioeconomic status set for them by their husbands. If social statuses are indeed contagious in nature, then in the case where the husband's occupational status is much higher than the wife could realistically achieve on her own (given her current occupational qualifications and current market conditions), her working at a low-status job would reflect poorly on the family's standing in the community. A socially acceptable solution to this problem for the wife, but not the husband, is to quit work. In sum, whether or not a wife works will depend on whether her occupation enhances or detracts from the family's socioeconomic position. Because many wives, unlike most husbands, have had the option *not* to work, they have the option—if not the obligation—not to have an occupation that would reflect poorly on their own or their family's position. If this is true, then the higher a woman's derived

socioeconomic position, the higher her occupation must be if she is to have a serious work commitment. Furthermore, it will be to the advantage of both the wife and her family if she can optimize her occupational status.

Just as giving up a much lower occupational status is more feasible normatively for the wife than the husband, so is the neutralization of the possibly negative consequences of a considerably lower status. For example, many women will not mind holding jobs that would not be commensurate with their present or expected future status as long as these jobs are considered short-term rather than providing a regular self-identifying adult role—working as a secretary, for example, while the husband is a medical intern or working to send the children to college. Other jobs which might be exceptions are those which can blend into avocations and which may be chic, though not necessarily remunerative. Of course, the social distance between a woman's occupational status and her derived social status cannot be too great.

In sum, I am arguing, first, that the status maintenance or enhancement concerns of the family produce pressures on the wife to work. Second, however, the same status considerations influence how serious and long-term her work commitment will be (if she does work) as well as her occupational level. The view presented here is that, for reasons of status maintenance, status *compatibility* among family members is essential although status *equality* is not so important. In terms of the wife's socioeconomic role in the family, this means that she is more likely to work if her potential occupational status—and its economic rewards—serve to *enhance* the family's socioeconomic status. On the other hand, if her relative economic contribution to the family were to be negligible and her occupational status much below that of her husband's, she would be less likely to work as there would be little net socioeconomic advantage to her and the family. Hence, arguing from the standpoint of the external status maintenance problems of the family, rather than the internal complications raised by competition *within* the family,

leads to quite different conclusions about wives' socioeconomic role than those of Parsons.

STATUS COMPETITION

If the family's status maintenance concerns encourage a positive socioeconomic role on the part of the wife, what about the supposedly disruptive competitive problems raised by Parsons? Parsons argued that the norm requiring the husband to be the main, if not the only status determiner and provider for the family while his wife is the homemaker is a functional imperative for marital stability in our society. In other words, such norms presumably developed and persist because if both husband and wife had important work attachments, disruptive competition would occur. Hence, he is arguing that competition is inherent in the situation where both spouses work and that sex-role norms are, in a sense, an *effect* of the competition inherent in the two-worker family. In fact, however, there are a number of reasons for arguing the reverse—namely, that such a norm itself creates conflict where none might otherwise arise. Furthermore, even if competition does develop at times, it may not be as serious a societal problem as Parsons maintains. Taking the latter case first, it is probably true that the potential for conflict undoubtedly will be the greatest when both husband and wife are in career-type occupations—occupations in which geographic mobility is often important, in which the occupation makes heavy demands on both the worker and his or her family (coping while the spouse is away on business or working overtime, business-related entertainment, etc.) and in which there tends to be a heavy ego investment in the occupational role. However, a good part of these conflicts arise out of the enormous and conflicting demands made on each career partner and not necessarily because the spouses are competing with each other for a higher status. Furthermore, competition, where it does occur, may be particularly severe at some points in the career cycle but not others. For example, an especially trying period for most people entering high-level occupations is the early stages where

competition among peers is heavy and few have yet found their niches. Nevertheless, regardless of these problems, the number of people in high-level careers does not represent a numerically important segment of our population. Thus, while it is true that relatively more men than women have "careers" rather than "jobs," it is also probably safe to say that most men, like most women, have "jobs" and not "careers." One might seriously question whether the occupational demands made on the average accountant, schoolteacher, engineer, craftsman or operative are such as to provide the disruptive, competitive features Parsons hypothesized.

Although complete sex-role segregation may be one mechanism for preventing competition, there are other buffer mechanisms which will have a similar effect without excluding wives from a significant work role. For example, one simple type of segregation mechanism places the spouses in different occupations or even in the same occupation but in different work environments. There are a number of ways this can protect spouses from competing directly with each other even if the socioeconomic levels of their occupations are comparable. First, if the pair are in different occupations, their co-workers and the community at large will have difficulty ranking them unless there are gross status inequalities. After all, unfamiliarity with all but very familiar occupations is one well-known problem with occupational prestige studies like the North-Hatt study (Reiss, 1961: ch. 2). Furthermore, the details of each spouse's income are not generally known to the community, making invidious comparisons even more difficult. Parsons' implicit assumption that people in different occupations—or even the same occupation—are typically in direct status competition with each other seems dubious. A more reasonable assumption is that competition among individuals is structured according to rather specific occupational or organizational work situations. Thus, workers in different occupations and even in the same occupation under different employment conditions operate in distinct competitive hierarchies which may be limited to a particular work organization or type of work

organization, a limited subsegment of the larger occupation, or a particular community. Furthermore, many of the rewards that signify the attainment of different prestige levels within the relevant occupational or organizational reference group vary among occupations and within occupations. For example, to what extent is success in academic medicine measured in the same way as success in private practice within a given community? How does one generalize, beyond the confines of a given organization, the meaning of the many subtle and nonmonetary ways in which bureaucratic organizations reward people at different hierarchical levels? In a sense, the occupational ranking systems sociologists have developed—useful as they may be for some purposes—are abstractions, while competition among individuals is a very concrete phenomenon embedded in very particular interaction situations. Hence, the extent to which people operating in different occupational or organizational reference groups directly compete can be rather limited even if they apparently are in competitive positions on one or more of the occupational scales currently being employed by sociologists.

The existence of different competitive hierarchies is particularly obvious in the historical tendency for men and women to concentrate in sex-labeled occupations (Oppenheimer, 1970: ch. 3). Even when the wife is in a white-collar occupation and the husband in a blue-collar occupation, the fact that she is in a traditionally female job will probably reduce the perceived competition between her and her husband.

An overlapping set of factors which will operate to protect working couples from disruptive competition arises from the sources of invidious comparisons. To the extent the evaluations of "significant others" are important in such conflicts, a variety of protective mechanisms may come into play. Since "significant others" often do not know enough to rank couples in different occupations and usually are unfamiliar with the particulars of each spouse's earnings, it is difficult for them to make comparisons. In addition, a community's evaluation of a couple is

based partly on the family's consumption patterns—i.e., its style of life—rather than the occupational sources of the income used for consumption. To the extent this is true, the pooled incomes of husband and wife permit a homogeneous level of socioeconomic status rather than two competing levels. Another way of presenting a "united front" to the community so that invidious comparisons are difficult is collaboration—being in business together or collaborating professionally.

It is interesting to note that in an essay first published in 1940 Parsons himself suggests that mechanisms similar to those discussed above may be operating to prevent invidious status comparisons among close kin. However, he refers to brothers rather than spouses. He argues that "the vagueness of our class structure provides a kind of cushioning mechanism" and that "so long as the discrepancy is not too great, it is then unnecessary for there to be any very exact determination of relatives' class status . . ." (Parsons, 1954a: 87–8). Parsons also thought that geographical separation was an additionally important factor.

For instance, if two brothers are on the faculty of the same university, the question of their relative status is very acute. But if one is a physician in Boston and the other is in business in Chicago, such questions hardly arise at all unless the discrepancy of their relative "success" is very marked. (Parsons, 1954a:88)

However, it seems reasonable to argue that, in the case of the physician and businessman brothers, the cushioning effect of the "vagueness of our class structure" would be operating even if they both lived in the same city. And if it could work for two brothers, the same mechanism may also operate in the case of working spouses.

It is probably true, however, that tensions may arise when the wife's earnings equal or exceed her husband's since money, unlike other status perquisites, tends to be a roughly universal measure of success.³ The question is whether any

³ Even here, however, one may argue that potentially damaging invidious personal comparisons may be defused by the recognition that the earnings of

stresses induced by the equal or better earnings of the wife are inherent in the situation or are a result of the traditional norms governing men's family roles. As long as the spouses' incomes are not too discrepant, there is a distinct economic advantage to the couple and the individual partners in both working and staying married to each other, no matter whose income is higher. The fact that a wife's equal or somewhat greater earnings is interpreted as a threat in spite of its economic utility to the couple suggests that it is the existence of the norm basing the husband's standing and authority in the family on his ability to be the major provider which leads to stress rather than any other inherent features of the situation.

Considering the norm requiring the man to be a good provider for his family as the possible "culprit" in some types of marital conflict casts a different light on Parsons' contention that the higher rates of marital instability in lower socioeconomic groups is due to the more frequent employment of wives (Parsons, 1949:193-4). As other researchers have pointed out, there is good reason to believe that a major factor in the considerable marital instability of such groups is not the wife's labor-force participation *per se* but, rather, the husband's inability to do his share because of chronic job insecurity (see, for example, Rodman, 1963; 1967: 214-5; Rainwater and Yancey, 1967: 65ff.). This is a very different situation from one in which two schoolteachers are

married or a regularly employed plumber has a wife who is a clerk typist.⁴

EMPIRICAL EVIDENCE

Contrary to Parsons' theories, we can expect wives to have a growing socioeconomic role in the family rather than a persistently negligible one. Also, problems of status maintenance will tend to lead to a relatively favorable comparison of husbands' and wives' socioeconomic status, rather than a much lower (and, thereby, presumably non-competitive) status on the part of the wife. Finally, I have suggested that Parsons exaggerated the amount of status competition which would necessarily arise in the two-worker family. The next issue is whether there is any empirical evidence that can help us choose between these two contrasting views of the nature of women's socioeconomic role in the family.

First, trends in female labor-force participation in the postwar period are more consistent with the view that socioeconomic pressures and opportunities have supported an increasingly important socioeconomic role on the part of wives than the view that women's economic roles must, of necessity, be minor. Women's work-rates have risen considerably at all stages of the family cycle (Openheimer, 1970; 1973). Furthermore, research in progress by this investigator indicates that the work rates of wives of white-collar workers rival those of blue-collar wives and that it is only the wives of the highest-level workers who exhibit somewhat depressed work-rates. However, such upper-middle-class wives showed some of the greatest increases in labor-force participation in the 1960-1970 period.

Second, research on the determinants of wives' labor-force status suggest that the greater the potential relative contribution of the wife, the more likely she is to work. This finding is hardly consistent with the stress Parsons puts on the wife

"successful" people in some occupations may not be in the same league as the earnings of an average worker in another occupation. That is, earnings differentials are a feature of occupations, not of the performance of individuals within these occupations and, hence, carry no personal stigma. Parsons (1954a:87) provides a rather nice example of this process when he compares a world-famous scientist in a university with a corporation lawyer:

so long as the scientist is able to maintain a "respectable" standard of living, entertain his friends well, dress his family adequately, and educate his children well, the fact that he cannot afford the luxuries of a hundred-thousand-dollar income is a matter of relative indifference. He simply does not compete on the plane of "conspicuous consumption" which is open to the lawyer but closed to him.

⁴ Divorce rates have been going up in recent years (see, for example, Glick and Norton, 1973), but whether this can be mainly attributed to work-induced competitive conflicts is doubtful.

making a negligible contribution to the family's socioeconomic status. Thus, using the 1/1000 sample from the 1960 census, Sweet (1973:91-2) found that the wife's education was positively related to her employment status. More importantly, perhaps, he found that her education had a greater effect on employment the lower her husband's income (Sweet, 1973:131). That is, if the husband had a relatively low or moderate income, high education on the part of the wife led to a higher employment rate than the same educational attainment would if her husband's income were high. The level of educational attainment of wives is usually interpreted by labor-force analysts as an indicator of her potential occupational and wage level (Sweet, 1973:51; Bowen and Finegan, 1969:53). Hence, Sweet's findings suggest that, where economic pressures for an additional income seem to exist, the greater the potential relative socioeconomic contribution the wife could make to the family, the more likely she was to be working. However, these findings do not appear to be consistent with Parsons' basic argument, as they are indicative of conditions that are most likely to result in similar (and presumably competitive) occupational statuses between husband and wife as well as a significant rather than a negligible socioeconomic contribution on the part of the wife.

Additional data on the socioeconomic contribution of wives come from preliminary results of an analysis of the 1970 Public Use Samples (PUS). The data are from a 3/1000 sample of white couples (Spanish descent excluded) where the husband was a household head, 18-64 years old and currently or last reported as working in a nonfarm occupation.

The sample of couples was divided into several socioeconomic groups based on the husband's occupation. In this way, all wives could be assigned a socioeconomic position regardless of their labor-force status, and it would still be possible to do a detailed comparison of the socioeconomic characteristics of husbands and wives.

One main problem was to find a suitable occupational classification system for the

men. The system, and its rationale, is explained in greater detail elsewhere (Oppenheimer, 1974). The major goal of the occupational classification system was to define a small number of occupational categories, each of which was relatively homogeneous and distinct with respect to certain important social and economic characteristics—mainly earnings and occupational type. The procedure followed was to examine the median 1959 earnings by age of men in each detailed occupation on which published data were available in the 1960 census (1970 data had not yet been published when the study began). This analysis of published data then was used to group the detailed occupations within each nonfarm major occupation group according to the peak 1959 median earnings among different age groups in that occupation. For example, the highest median 1959 earnings of Accountants and Auditors were for men aged 45-54 years old and were \$7,615. Hence, Accountants and Auditors were classified into the Group II Professions—those professional occupations with peak 1959 median earnings in the \$7,000-8,999 range. All detailed occupational categories were classified in a similar way—into peak median earnings groups within major occupational groups. Then the men in the PUS sample were classified into one of these categories on the basis of their current or last occupation. For the 1970 PUS, the same occupations were classified in exactly the same way, regardless of their 1969 earnings—at least to the extent this was possible, given the numerous changes in the 1970 detailed occupational classification system (U.S. Bureau of the Census, 1972). In this fashion, an occupational classification scheme was created which measured the general earnings level of the occupation as well as preserving important differences within earnings groups—namely the occupational type, such as professional or managerial. The same occupational classification system was used for the wives.

The findings are relevant to two major aspects of the theoretical alternatives under discussion in this paper. First, there is the extent of the socioeconomic contribution wives make via their economic

contribution to the family. The question at issue is whether or not this contribution is so small as to be negligible in a "status-determinant sense." Second, there is the question of the joint occupational characteristics of husbands and wives. Are wives' occupations uniformly at a lower status level than their husbands' or is there, instead, evidence of status similarities with, perhaps, certain minimum acceptable occupations for wives? Moreover, is there any evidence of labor-force selectivity for wives at different occupational levels? Are wives who might operate at a supposedly competitive level with their husbands more likely to have dropped out of the labor force (consistent with Parsons' theories) or are such wives more likely to be working, and the drop-outs more likely to be among those whose occupational level might have a minor or negative impact on the family's socioeconomic status (the argument presented in this paper)?

The Wife's Economic Contribution

What is the nature of the wife's socioeconomic contribution to the family? Let us first consider wives' economic contributions and how these affect the socioeconomic status of their families. A wife's earnings will undoubtedly affect the general status position of the family and not just its economic position because the wife's earnings will probably modify the family's consumption patterns (i.e., its life style), which are an important factor in the community's evaluation of the family's status. It is interesting to note that Parsons himself stressed the importance of money as a criterion of status, especially in view of the fact "that its expenditure is largely for other symbols of status in turn" (Parsons, 1954a:85). Sociologists have been able to avoid seriously considering life style as an independently important determinant of social status because the assumption typically has been that only the husband makes an important socioeconomic contribution to the family. Hence, only his occupation will determine the family's income and its resulting style of life. Since occupation has appeared to be a good indicator of socioeconomic

status for other reasons as well (e.g., occupational prestige), there has been little motivation to go beyond the consideration of the husband's occupation alone. However, when serious consideration has to be paid to the possibility of two incomes in the family, then the *status* impact of the second income, as well as its *economic* impact, can no longer be safely ignored (for discussion of this problem, see also Barth and Watson, 1967; Duncan, 1961:118).

The issue of the working wife's economic impact on the family's socioeconomic status does not involve just the question of whether wives make an impact but the whole question of the criteria used to decide whether that impact is significant or not. In other words, just how large do the wife's earnings have to be for her employment to have an impact on the family in an economic or "status determinant sense"?

Table 1 shows the ratio of the median earnings of wives to those of husbands for couples where both spouses had net positive earnings in 1969 and for families where wives had extensive work experience during the year. It indicates that the lower the occupational earnings group of the husband, the higher the ratio of wives' median earnings to husbands'. This is true for couples where the husband was a white-collar worker as well as those where he was a manual or service worker. For example, among professional husbands, the ratio of median earnings of wives to husbands rises from 28 percent for Professionals I to 43 percent for Professionals III which is a higher ratio than for several manual groups. The ratios are even higher, of course, when considering couples where the wife appeared to be working full time most of the year, although a relatively small proportion of couples fell into that category. Where the husband was in a Professional I occupation, for example, the ratio of median earnings went up to 50 percent if the wife had worked full time.

Although wives' earnings start to approach those of husbands in the middle and lower occupational groups, women still earn considerably less than their husbands. Given this fact, the question is

Table 1. Wives' 1969 Median Earnings as a Percent of Husbands', by Husband's Occupation and Wife's Work Experience: White Couples, 1970*

Husband's Occupation	Ratio of Wives'/Husband's Median Earnings (Percent)		Percent of Families with an Earning Wife

* Two groups of wives with net positive earnings were considered: (1) "All"—all wives with earnings; and (2) "Full-time"—those wives who worked 40–52 weeks in 1969 and 35 or more hours in the week before the census. Forty weeks was selected as the minimum for "full-time" employment in order not to exclude teachers.

whether the contribution of wives can really have a "status determining" impact on their families. The implication of Parsons' argument is that the wife's earnings are not important because they do "not produce a comparable proportion of the family income" (Parsons, 1949:194). The traditional absence of concern regarding wives' earnings in stratification research indicates that this view has been generally shared. However, this approach is inconsistent with the criteria usually employed

in stratification research to determine socioeconomic status and social mobility. No scholar has maintained, for example, that social mobility only occurs when a man moves from one occupation to another that pays at least twice as much. Hence, to assume that the wife's income must be equal to her husband's for it to have an effect confuses the difference between making an impact on the family's socioeconomic status and making the same impact as the husband does.

A comparison of the median 1969 income of families where the wife had earnings in 1969 to those where she did not provides a rough indication of the impact of wives' earnings on their families (Table 2). Such a comparison shows that the earnings of a working wife (regardless of the amount of time worked) frequently are sufficient to provide a functional income substitute for upward occupational mobility on the part of the husband. Thus, the median family income was higher for families of Professional III men *with* earn-

ing wives in 1969 than for the families of Professional II without earning wives. Families of men in the Manager III group who had an earning wife all but closed the gap between themselves and the families of men in the Manager II group who did not have wives with earnings. This is the case generally: the earnings of the wife usually puts the family in the next higher income group. If the wife worked 40-52 weeks in the year and 35 or more hours in the week before the census, her impact was even greater, of course. For example,

Table 2. Median 1969 Income of Families by Husband's Occupation and by Earnings Status and Work Experience of Wife: White Couples, 1970 ^{a, b}

^a Median income in dollars of families with net positive incomes.

^b Two groups of wives with net positive earnings were considered: (1) "All"—all wives with earnings; and (2) "Full-time"—those wives who worked 40-52 weeks in 1969 and 35 or more hours in the week before the census. Forty weeks was selected as the minimum for "full-time" employment in order not to exclude teachers.

for such families, if the husband was a Craft III worker, the family income went up to \$13,668—more than the income of families of Professional II men who did not have wives with earnings in 1969.

Furthermore, such figures actually *understate* the impact of the wife's earnings on the family's income because the income of husbands of nonworking wives is typically higher than that of husbands of working wives. For all occupational groups combined, for example, the median 1969 income of husbands of wives with earnings was only 86 percent of the median income of husbands of wives without earnings. Hence, the husband's dollar share of the family income for couples where the wife had earnings was less than in families where the wife did not work.

In sum, the evidence indicates that whether or not wives worked extensively during the year and in spite of the fact that their median earnings were not comparable to the earnings of husbands, wives' earnings were high enough, on the average, to have a considerable impact on family income—enough, in many cases, to eliminate the income difference between a working wife's family and the family of a man in a much higher paying occupational group whose wife did *not* work. Therefore, in assessing the impact of the working wife's income on the family's socioeconomic status the most important issue is *not* whether her earnings equal those of her husband's but the extent to which her earnings provide a functional substitute for upward occupational mobility on his part or a counterbalance to downward mobility.

Status Compatibility of Husband's and Wife's Occupations

By and large, data on the joint occupational characteristics of husbands and wives support the view that status compatibility is an important factor, since relatively few wives and husbands are at highly distinct occupational levels (Table 3). Furthermore, the data even suggest that it is more important for the wife to have an occupation which reflects favorably on the status position of the family

rather than one which guarantees a low profile. Thus, a very small proportion of the wives of white-collar men are found in blue-collar or service occupations. For example, while 17 percent of all employed wives were in manual occupations and 15 percent in service occupations, only three percent of Professional I wives were in manual occupations and six percent in service occupations.

Most wives of white-collar men were to be found in middle-level occupations—that is, the status difference between themselves and their husbands was not too great. Professions, especially the lower-paid professions (i.e., many of the female professions) were particularly important for the wives of professionals. For example, while only 18 percent of all employed wives were in professional occupations, 47 percent of the wives of Professionals I and III men and 33 percent of the wives of Professional II men were in the professions. In general, the wives of white-collar men were much more likely to be in professional and technical occupations than the wives of manual workers. In addition, for all white-collar wives clerical occupations were of great importance, with the proportions in these occupations varying from 32 percent for the wives of Professionals III to 47 percent for the wives of Sales II and Clerical III men. In sum, the wives of most white-collar men do not seem to be working in occupations at a considerable status distance from their husbands'.

White-collar couples in which the greatest amount of status discrepancy is evident are those where the husband was in a Group I occupation. Although relatively few of the wives of Group I Professionals or Managers were in blue-collar or service occupations, it was also true that not many were in occupations at the same or adjacent earnings levels to their husbands. This is particularly true for the wives of men in the Managers I and II group. These patterns certainly appear to be consistent with Parsons' notion that the risk of status competition leads to the avoidance of this type of situation. However, they are also consistent with my view that such competition is most serious for higher-level workers. Furthermore,

given women's socialization against strong occupational commitments and given the many other difficulties and obstacles involved in entering a high-level male occupation and combining it with marriage and a family, one would not really expect a high proportion of the wives of upper-white-collar males to be working at a comparable occupational level. This is especially true, given the variety of alternative activities available—both work and nonwork—which provide the opportunity for nonfamilial involvements but which make the total demands on the woman less monumental in character.

While relatively few wives of Group I or II men are in high-level occupations themselves, the data indicate that if a high occupational level is achieved there is little evidence of withdrawal from work to

avoid competition with the husband. Although occupational data on actual withdrawal from the labor force are not available, information exists on women in the labor reserve—those women not currently employed who have worked in the ten years preceding the census. Presumably, women in "status-threatening" positions will be more likely to drop out of the labor force in order to preserve their marriages and, therefore, we can expect to find some evidence of a buildup of such women in the labor reserve. Table 4 shows the current or last occupation of all wives who were working or who had worked at some time during the ten years preceding the census—women we shall call "recent workers." The measure used is the proportion of recently-working wives in a given occupation who were

currently employed. To the extent that women drop out of the labor force because they are in status-threatening jobs, we would expect the proportions in the table to be low. On the other hand, if such jobs are not really a deterrent but are actually advantageous, the dropout rates should be low and most of these women will be employed. In that case, the proportions will be high. Unfortunately, women who move into less status-threatening occupations rather than dropping out of the labor force entirely cannot be detected. In addition, marriages that break up due to these status conflicts cannot be detected from these data either.

As Table 4 indicates, there is little evidence of a selective dropping out of women most recently in higher-level occupations; in fact, just the contrary. While only 48 percent of all recently-working

wives of Professional I men were currently employed in 1970 (compared to 57 percent for all wives), the proportion goes to 64 percent for those whose current or last occupation was in the Professional I and II groups.⁵ In general, for women in both the Professional I and II groups and the Managers group, the proportions employed were higher than for all wives. This also generally holds for all occupation groups of the husband where sample size is sufficient to permit measurement. For example, while only 56 percent of all the recently-working wives of Managers I and II men were employed, the proportion was 62 percent for those whose current or

⁵ When the Professional I and II groups are considered separately, the proportion of wives of Professional I men recently working in a Professional I occupation and who were employed in 1970 goes up to 71 percent.

last occupation was in the Professional I and II group.

In sum, there is little evidence of a substantial reservoir of non-employed women in high status occupations among the recently-working wives of upper-middle-class men—women who presumably dropped out of the labor force to avoid competing with their husbands.⁶ On the contrary, the reverse seems to be the case. Higher-level wives are more likely to be employed and wives whose most recent jobs were in the lower-white-collar occupations were less likely to be employed. For example, for wives of Professional I men, only 32 percent of those who were most recently in the Sales III category were currently employed.

Turning to the wives of manual and lower-level service workers, there is evidence that these couples seek to maximize the socioeconomic benefits of the wife's employment rather than ensure that it is at a low, nonthreatening level. This is indicated mainly by the high proportion of such wives in white-collar occupations—particularly the clerical occupations (Table 3). Not counting the Service III men, who are probably better included among non-manual workers (these are men in the protective services), the proportion of wives in clerical occupations varies from 27 percent for the wives of Service IV men to 40 percent for the wives of Craft III men. This compares to a range of 32 to 47 percent for the wives of white-collar men. Hence, the differences are not exceptionally great, especially when we consider the lower educational level of the wives of blue-collar men.⁷ Nor are these clerical wives of manual workers mainly concentrated in the lower-level Clerical IV occupations. This is a relatively unimportant occupational group for the wives of both manual and nonmanual men. Further-

more, data not reported here in tabular form indicate that there is little difference between the median earnings of clerical-worker wives of men in both high and low-level occupations. For example, the 1969 median earnings of full-time, 40+ weeks, clerical-worker wives of Professional I men were \$5,221 as opposed to \$5,086 for the wives of Craft III men, \$5,076 for the wives of Service IV men and \$4,771 for the wives of Operative IV men. The total range in medians was only \$637. However, the typical differences were usually much less—for example, the difference between the medians for the clerical-worker wives of Professional I and Craft III men was only \$135. In sum, there is little evidence that the clerical group is highly differentiated with the wives of white-collar men at the top of a pronounced hierarchy and the wives of blue-collar men clustering at the bottom.

Although small sample sizes raise some problems, the data on labor-force withdrawal indicate that, for the wives of manual as well as nonmanual workers, higher-level occupations seem to exert a strong motivation to stay or return to work (Table 4). Women whose most recent occupation was in the Professional III group provide a particularly interesting case. Very high proportions of these wives were currently employed for most occupation groups of the husband. Among wives of blue-collar or service workers, fully 70 percent or more of the wives in the Professional III group were currently employed for all occupational groups of the husband. Among the wives of white-collar men, however, the situation is somewhat different. If the husband was in a Group III occupation and the wife most recently in a Professional III occupation, then the proportions employed were also relatively high—72 percent for the Professional III wives of Professional III men, for example. However, where the husband was in a Group I or II occupation, the attraction of the Professional III occupation for the wife seems to be less. For example, for the wives of Professional I men, only 50 percent who had most recently been in a Professional III occupation were employed at the time of the census.

⁶ In addition, preliminary results of a multiple regression analysis on the 1970 data indicate that the greater the potential relative socioeconomic contribution of the wife compared to the husband (as measured by relative educational attainments), the more likely she was to be working in 1970.

⁷ For example, while 77 percent of the wives of white-collar men in 1970 had completed 12 or more years of schooling, the proportion was only 48 percent for the wives of blue-collar and service men.

In sum, the data on the employed/labor-reserve status of wives in different occupations indicate that the higher the socioeconomic level of the wife's occupation, the more likely she was to be currently employed. Thus, there is little evidence here of a marked dropping out of wives in potentially status-threatening occupations.

CONCLUSION

The major goal of this paper has been to evaluate critically the theoretical merits of some of Parsons' ideas regarding both the nature of women's socioeconomic role in the family and the determinants of this role. In doing this, the paper has suggested that alternative views concerning women's socioeconomic role and the forces shaping it are more theoretically appealing as well as more consistent with the evidence regarding the extent and nature of women's work behavior.

First, the argument developed here is that we must view families as units in the stratification system, not just as small groups faced with the internal problems of maintaining good relations among members. When we place the family in the context of the larger stratification system, we see that one concern of families will be status maintenance and status enhancement. To the extent this is true, wives can have a potentially valuable socioeconomic contribution to make to their families' competitive position. Therefore, there should be rather powerful, and probably growing pressures for wives to work. Moreover, the evidence certainly indicates that wives have been increasing their labor-force participation for a number of years.

Second, the argument presented here is in agreement with Parsons concerning the importance of status consistency—or at least status compatibility—in family stability. However, from a theoretical point of view, this paper has suggested that Parsons' preoccupation with competition has led to a distorted analysis of the problem of status consistency within the family. An alternative proposed here is that for reasons of status maintenance, status compatibility among family members is

important. This means, however, that negative consequences will ensue if the wife has a much *lower* as well as a much *higher* socioeconomic status than the husband. Hence, depending on her personal qualifications and on market conditions, if she can make a positive contribution to the family's socioeconomic position, her labor-force participation is encouraged. As a result, wives who are working generally will be in occupations that reflect favorably on their families' socioeconomic position as derived from the husband. Data from the PUS indicate that there is considerable empirical support for this position. The socioeconomic distance between the occupations of husbands and wives was particularly pronounced only for wives of men in the highest level occupations. Even here, highly discrepant manual or service occupations are avoided by these wives. Other evidence contradicting the view that a lower-level occupation is a functional necessity of the working wife comes from an examination of the occupations of recently employed wives. Recent workers in relatively high-level occupations are more likely to be currently employed than recent workers in lower-level occupations.

The PUS data indicate that although wives earn considerably less, on the average, than husbands, wives' economic contribution to their families can still be highly important—enough, in many cases, to provide a functional substitute for upward occupational mobility on the husband's part, or to compensate for a husband's relatively low earnings compared to other men in his occupational group. Thus, the unfavorable earnings position of women versus men in our society should not prevent us from recognizing the economic significance of wives' earnings, low though they be.

Regarding competition, I have argued that Parsons greatly overestimated how disruptive it would be if both the husband and wife worked. For a variety of reasons, competition is less of an important factor than Parsons maintained. Working spouses usually operate in different occupational and/or organizational work groups which protect them from direct

competition with each other. Conflicts are most likely to arise between husbands and wives in very high-level occupations. However, high-level couples—and especially high-level working wives—are a relatively small segment of the population. Finally, this paper suggests that rather than traditional sex-role norms being a teleological result of the conflicts inherent in the two-worker family, they may be a major factor in the cause of such conflicts when the wife works.

THE CHANGING AMERICAN FAMILY FROM THE PREINDUSTRIAL TO THE INDUSTRIAL PERIOD: A FINAL REPORT

HERMAN LANTZ MARTIN SCHULTZ MARY O'HARA

Southern Illinois University, Carbondale

American Sociological Review 1977, Vol. 42 (June):406-421

This report represents the completion of a content analysis of magazines designed to examine the American family from 1741 to 1865. The final report compares the last period, 1850-1865, with previous periods and includes a new discussion of family conflict in magazine content. It is suggested that the period 1850-1865 may have been a period of significant family change. The theoretical synthesis of findings for the 1741-1865 period is presented. Significant variables include the family as a change agent and the role of ideology and developmental factors (i.e., urbanization and industrialization). Some observations on causal relationships are made and basic limitations in the use of literary sources of data are noted.

This report represents the completion of a content analysis of magazines designed to examine the American family from 1741, essentially a preindustrial, pre-urban period, to 1865, a period in which large-scale industrialization was well under way. Three earlier reports (Lantz et al., 1968; 1973; 1975) dealt with the important findings for each of the periods. The essential focus of each of these studies was to examine power patterns between the husband and wife, the extent to which romantic love was important, motivations for marriage, and sanctions for sexual deviance. The results of the final period, 1850-1865, deal with each of the above plus an analysis of the

additional dimensions of conflict between parents and conflict between parents and children. These facets of family dynamics had not appeared in the magazine content in our earlier investigations, and this appearance of family conflict represented a new and possibly significant element to explore.

The purpose of this final paper is to compare the findings of the three earlier periods with the final period, 1850-1865, and to present the theoretical implications of the entire project. The data for each of the earlier time periods was taken from Mott (1930), who has broken the development of magazines into distinct periods. As described in our earlier re-

ports, each period has its special social, political and economic characteristics. The final period is characterized by Mott (1938) as one of significant change in the American magazine, as well as in American society. Nearly all important novelists, poets and critics made frequent contributions to magazine literature. Mott indicates that during this period magazines were a major force in the diffusion of democratic and equalitarian ideals. Content of the periodicals cut across social backgrounds and classes more than in earlier periods (Mott, 1938:46-101).¹

Perhaps the most noteworthy characteristics of magazines for the period 1850-1865 were the intellectual issues and debates which emerged. There was a general questioning of the position and authority of the male. The interpretations of Marxist writings, along with the writings of utopian socialists, appeared in literary works and magazines. Utopian efforts sprang up in America during the period and some, such as the Oneida community, had their own magazine, *The Oneida Circular*, which expounded spiritual, sexual and economic equality (Mott, 1938:207). The Civil War also brought into focus greater demands for social, political and legal equality. In addition to the slavery issue, women's rights received considerable attention. Frequently women's rights and the civil rights of blacks were discussed in the same article, indicating a more encompassing view of equality (Mott, 1930:50). The social issues of the period 1850-1865 were significant for changes in American society as a whole, and the changes could have had a bearing on what was happening to the family.

Source, Method and Procedure

Mott (1938:218) lists 71 important magazines for the 1850-1865 period.² Of these

magazines, 36 were included in our analysis.³ Of the 35 magazines not represented in our sample, at least 21 magazines (possibly more) had specialized content that clearly was not reflective of family patterns, one magazine emphasized foreign literature and thirteen magazines could not be located. The sample for this last period consisted of all available issues of the 36 magazines that were published from 1850-1865. All available issues were examined in order to eliminate any sampling error. Our data for the 1850-1865 period are based on our observations from a total of 6,559 issues which we examined.⁴

The procedure for examining the magazines was the same as for earlier periods. The table of contents for each periodical issue was carefully scanned. Article titles or descriptions were used as the basis for initial selection; any article which appeared to involve one of the topics or issues under consideration was included. We were guided by titles and we also examined the first few paragraphs of the articles because titles were not always informative enough. If the first page of the article contained information on one of the variables we were coding, the entire article was examined and the appropriate tabulations were made. If none of the topics was found on the first page, the article was dismissed. Reliability was established by applying the criteria for classification in a consistent manner. The schedule and

influential magazines of each period have been examined. For a detailed discussion of the historical periods designated by Mott, the nature of a magazine and the character of an important magazine, see Lantz et al. (1968:414-6).

³ The titles and dates of these magazines for the 1850-1865 period can be obtained by writing to the senior author.

⁴ It is important to keep in mind that the number of issues examined for the different time periods varies considerably. Even though the earlier periods were considerably longer in terms of the length of years covered, the number of issues published and examined in these earlier studies was much smaller. For the various periods, the number of issues represented in our reports was: 1741-1794, 546 issues; 1794-1825, 2,373 issues; 1825-1850, 5,334 issues; 1850-1865, 6,559 issues. For a discussion of the tremendous expansion of periodicals during the 1800s, see Mott (1930).

¹ See Mott (1938:10-3) for more extended comments on the circulation of periodicals during this period.

² It should be emphasized that the populations in all four of our studies are based on the list of magazines designated as important by Mott. It is only because of his work that the reasonable and significant assumption can be made that the most

specific categories facilitated this procedure.⁵

The unit of analysis was the explicit discussion of one of the variables. While more than one discussion of the same variable could come from the same article, this seldom happened except in the case of discussions of power and romantic love. A schedule was used which allowed for the duplication of the tables used in the earlier studies. These tables concern power in the man-woman relationship, romantic love, motivations for marriage, and sanctions involving premarital or extramarital sex. In addition, tables were constructed to include discussions of conflict in husband-wife and parent-child relationships.

Our analysis for the 1850-1865 period involved an examination of the frequency and proportion of observations presented in the various tables.⁶ With regard to comparisons between periods, we have reported estimates of the average number of issues examined for any one particular type of discussion (e.g., one discussion of romantic love for every 5.4 issues examined). This method is useful in providing a basis for determining the relative amount of attention devoted to particular topics in the magazine literature during the four periods.⁷

⁵ For a discussion of Sebald's observations on this approach, see Lantz et al. (1968:416).

⁶ We also recorded the sex of the magazine editors and the authors of the discussions which we examined. Our analysis indicated that our study displayed a selective preference for female authors, but that male editors were clearly predominant. Thus, while female authorship may have skewed our findings in one direction, the predominance and control which male editors exercised over the final version of the published material would seem clearly to offset the possibility of serious bias resulting from an overrepresentation of female writers.

⁷ In our earlier studies, chi-square goodness-of-fit tests were used to facilitate comparisons within these tables. Since we were unable to obtain some of the magazines for the 1850-1865 period, the assumption of a random sample could not be justified and we have not reported the significance levels of the findings.

With regard to estimates of the average number of magazines examined per unit type of discussion, some cautions are necessary. Magazine content became increasingly specialized in the nineteenth century, and some of the periodicals for the latter periods contained relatively few discussions of the

Power in the Man-Woman Relationship

Various aspects of the power relationship between males and females during the 1850-1865 years were investigated. Power, as in previous studies, was defined as the ability of one individual to dominate another or others, to coerce and control them, obtain obedience, interfere with their freedom and compel their actions in particular ways. Power was coded as being exerted overtly by the male, overtly by the female, subtly by the female, or by males and females cooperatively.⁸

The data from our literary analysis of power in the man-woman relationship are presented in Table 1. Our attention was first directed toward a comparison of those discussions in which power was exerted overtly by the male and female. During this period, we recorded a total of 227 such discussions in the male category and 757 discussions in the female category. When the male-female totals were examined in the five individual categories of *existing* power, our data revealed that there was little difference in the number of discussions involving males (N=77) and females (N=54) as the source of power in the general power category. In regard to the four remaining categories, there were considerably more discussions of overt female power over morality, in courtship situations, over finances and in other areas. With respect to power in other areas, discussions centered on female power in the literary, intellectual and educational fields as well as in domestic and child-rearing situations.

Shifting our focus from existing power relationships to those discussions which *advocated* that overt power should be held by males or females, Table 1 indi-

issues which we analyzed in our research. It is also possible that, as magazines expanded from quarterlies to monthlies, bimonthlies or weeklies, the size of the issues decreased in some cases. While we do not believe that these changes seriously distort the rates we have reported, it is important to note that these rates should be interpreted only as crude estimates of the relative amount of attention given to different topics in the various time periods.

⁸ Instances of subtle male power were rarely discussed in the magazine literature and the few discussions we observed have been omitted from our analysis.

Table 1. Various Dimensions of Power in the Man-Woman Relationship and Source of Power by Character of Discussion (Fiction or Nonfiction), State of Power (Advocated or Exists) during 1850-1865 (in Number of Discussions)

cates that a majority of the discussions advocating power in general involved women (64%) as compared with those discussions advocating power in general on the part of men (36%). While the number of discussions advocating female power over morality was not large ($N=12$), we recorded only one discussion advocating male power over issues related to morality. We also observed considerably more accounts calling for overt female power over financial matters as well as in the miscellaneous category.

Overt Male Power Compared with Overt and Subtle Female Power

Evidence for a shift in the distribution of power between men and women can be given additional credence by examining what was taking place in the area of subtle female power. As in our previous studies, subtle female power refers to situations where the female is in control even though the male may be unaware that he is being manipulated. Since we were basically interested in the overall power of the male and female, the discussions which indicated either overt or subtle female power were combined to permit comparison with discussions of male power.

We recorded 227 discussions of overt power by the male and 1,015 discussions of female power (subtle and overt) across all five categories (see Table 1). When comparing the male-female totals within the *Exists* columns of the individual categories, we found that there were slightly more discussions of female power in general ($N=104$) than male power in general ($N=77$). In the four remaining categories, our analysis revealed considerably larger percentages of discussions of female power in each case: power over morality (99%), power in courtship (81%), power over finances (84%) and power in other areas (96%).

We also compare data involving discussions which advocated overt male power with those which favored overt or subtle female power. With respect to the discussions of power in general, a greater number of discussions advocated overt and subtle female power ($N=170$) than male power ($N=85$). Almost all of the dis-

cussions concerning power over morality involved women. While the total number of discussions advocating power in courtship was rather small, our findings revealed a considerable majority of discussions advocating female power in both of the remaining categories: power over finances (92%) and power in other areas (91%).

A disproportionate share of these discussions came from predominantly female- and family-oriented magazines. Thus, it is possible that these periodicals might have exaggerated the changing roles of the sexes as well as the influence and power of women during this period. Mott (1938) notes, nevertheless, that these periodicals endured because they reflected the ideas, interests and concerns of the magazine subscribers and readers.

Perhaps the most compelling evidence of changing ideas about the power of men and women in mid-nineteenth-century America emerges from the variety of discussions of overt female power in the educational, intellectual, literary, political and legal fields.⁹ The intense debate over women's rights during these years would seem to demonstrate that the threat to the traditional order was often taken quite seriously. One male writer, for example, was so incensed over the state of affairs that he advocated the inauguration of a "Man's Rights Convention" to combat

⁹ If we had anticipated such a large number of discussions of female power in so many different areas during this period, we would have been better prepared to categorize and tabulate these discussions within more specific dimensions and areas of influence. Since individual discussions were not identified at the outset of the research, the following percentages should be viewed as approximate estimates of the number of discussions in the miscellaneous category. Discussions of female power in the *Existent* category included: literary power, or the ability of women to influence others through literature (26%); intellectual power, or the influence of women through reasoning, knowledge and intelligence (26%); power in formal education, especially as teachers (24%); power in child-rearing (20%); power in terms of legal rights or political influence (4%). Discussions *advocating* female power consisted of the following: political power and legal rights to vote, run for office, hold property, etc. (40%); intellectual power (21%); power in child-rearing (18%); power in education (15%); literary power (6%).

Table 2. Total Row Sums of Power in the Man-Woman Relationship by Source of Power and Time Period

Source of Power	Time Period			
	1741-1794	1794-1825	1825-1850	1850-1865
Overtly by Male	136 (42%)	33 (29%)	199 (31%)	227 (17%)
Overtly by Female	42 (13%)	15 (13%)	147 (22%)	757 (56%)
Subtly by Female	105 (33%)	35 (31%)	193 (30%)	258 (19%)

"force with force" (*Littell's Living Age*, 1859:774-7).

Power in Man-Woman Relationship: a Comparison of Trends

The following analysis may serve to clarify the changes in family power which provoked so much debate in the second half of the nineteenth century. A comparison of the number of discussions of power and the proportion of discussions in each category for the different time periods is reported in Table 2.

We should consider first the large number of discussions dealing with power in the man-woman relationship in the 1850-1865 period. In fact, we recorded more discussions of power during this fifteen-year period (N=1,348) than in all three earlier periods combined (N=1,086).¹⁰ This finding may be especially important, given that we were not able to examine all magazines for the period. The difference in number of discussions was largely accounted for by the high number of nonfictional discussions recorded from 1850-1865 (N=1,002)

compared with nonfictional discussions for all previous periods (N=455). The attention which nonfiction writers devoted to commentaries on power in the man-woman relationship would seem to provide an important index of the interest and concern which these issues provoked in the mid-century years.¹¹

When we focus attention on the actual expressions and distribution of power, three distinct trends emerge in our literary analysis. The first trend involves a change in the expression of power. In the earlier periods (especially from 1741-1825), authority was normatively ascribed to the male, but magazine content revealed that power was not exclusively exercised by the man. Through subtle persuasion and indirect means for gaining influence, women were able to exert considerable power in matters of morality, courtship, child-rearing and other domestic situations. From 1825 to 1850, the expression of power began to change in the magazine discussions. As the percentages in Table 2 demonstrate, a trend from subtle to overt female power was greatly intensified in the 1850-1865 period.

The second pattern revealed in our content analysis for the several periods indi-

¹⁰ While we are impressed by the considerable amount of attention given to discussions of power in the man-woman relationship during the 1850-1865 period, the absolute number of discussions can be somewhat misleading. The absolute number and rates for the various periods are useful here: 1741-1794, 321 discussions or about one discussion for every 1.7 issues examined; 1794-1825, 113 discussions or about one discussion for every 21.0 issues examined; 1825-1850, 652 discussions or about one discussion for every 8.2 issues examined; and 1850-1865, 1,338 discussions or about one for every 4.9 issues examined. On this basis, the first and last periods represented the most attention to power in the man-woman relationship in terms of the issues which we analyzed.

¹¹ The fantasy and sentimentality of many fictional accounts often present monumental problems in making valid inferences about social reality. The importance of the nonfictional discussions in the later period stems from the greater probability that these discussions reflect realistic issues and situations in the man-woman relationship during the mid-nineteenth century. The substantial number of discussions involving existing power arrangements (N=858) compared with those advocating different sources of power (N=490) would further reinforce our conclusion that important changes were in progress during these years.

cates that female power grew in scope, involving new areas from one period to another.¹² From 1741–1825, discussions of female power were primarily restricted to the family environment and courtship situations. Female power in general or women's rights and influence outside the home were seldom discussed and rarely advocated in the periodical literature of the earlier periods. After 1825, however, these issues and topics became more common. The taken-for-granted nature of traditional roles was challenged by a growing controversy over the rights and responsibilities of women in the world outside the area of the family.

The third trend in our data involves discussions of mutual cooperation in the man-woman relationship. The data in Table 2 indicate that the percentage of discussions of mutual cooperation reached a peak from 1794–1825, and then declined considerably in relation to discussions of other types of power in the periodical literature from 1825–1865. This trend was especially evident in the magazine literature from 1850–1865 when only 8% of the discussions were classified in the mutual cooperation category. The explanation for a decline in the proportion of discussions involving mutual cooperation is interesting and deserves special comment, especially since we previously identified the pattern of mutual cooperation as one aspect of a move away from patriarchal dominance of the family. If one views the changes in family power in terms of an ongoing process, the concern for mutual cooperation in the eighteenth- and early nineteenth-century periodicals could have represented one phase of a move toward greater female power. By the middle of the nineteenth century, however, the emphasis for women was less on mutual cooperation, which may have been achieved in some respects, and more on additional dimensions of female power. The phenomenon of rising expectations on the attainment of power for women may also have been operative.

¹² The following discussion is based on an analysis of the distribution of power in the man-woman relationship. The specific data concerning the respective areas of power can be found in the three articles dealing with earlier periods.

Women had been achieving greater authority and power in earlier periods. Yet changes in the distribution of power and authority, once started, may have moved at a relatively slow pace. This tension for women concerning the realization of some measure of power, in a context in which the process of further power changes was inevitably slow, may have become intensified by the middle of the nineteenth century. This may help explain why the matter of the distribution of family power and authority was the dominating issue in magazine content of family life in the 1850–1865 period. If this interpretation is valid, this period could have been a crucial one in which basic changes in the power structure of the family were taking place, changes which set the direction and orientation of the family for a long time. In this sense, some of the basic changes which led to the contemporary democratic-companionship family of the twentieth century were greatly accelerated in America in the 1850–1865 period.

Conflict in Family and Marital Relationships

The data we have presented on changes in family power structure could have additional meaning if we examine the area of conflict for the period 1850–1865. The presence of conflict may have been a factor which helped to produce change.¹³

The same procedures for the selection of articles were used as in our analyses of power, romantic love and so forth. Overt conflict was defined as a situation (or situations) in which sharp disagreement and tension resulted from antagonistic interests, ideas or behavior. Covert conflict involved the presence of latent tensions, but tensions not openly acknowledged by any of the members involved. The data from our analysis are shown in Table 3.

Overall, our findings show 197 explicit

¹³ Since we did not collect information on family conflict in the earlier periods, we do not have a baseline to compare our findings for the 1850–1865 period with earlier years. With regard to marital conflict, however, a number of other writers (Furstenberg, 1966; Barnett, 1968) have noted that the topic was not openly discussed to any large extent until the middle of the nineteenth century.

Table 3. Various Dimensions of Conflict in Husband-Wife and Parent-Child Relationships by Character of Discussion (Fiction or Nonfiction) and Type of Conflict (Overt or Covert) during 1850-1865 (in Number of Discussions)

Source of Conflict	Conflict in General 1850-1965			Conflict over Domestic Roles 1850-1865			Conflict over Finances 1850-1865			Conflict in Other Areas 1850-1865			Row Sums
	F	N	T	F	N	T	F	N	T	F	N	T	
Overt between Husband and Wife	38	22	60	4	4	8	8	2	10	22	2	24	102 (52%)
Covert between Husband and Wife	23	14	37	5	1	6	5	0	5	9	0	9	57 (29%)
Overt between Parents and Children	7	5	12	0	0	0	0	0	0	13	5	18	30 (15%)
Covert between Parents and Children	3	4	7	0	0	0	0	0	0	1	0	1	8 (4%)
	N=197 (100%)												

discussions of family conflict for the 1850-1865 period. Nearly half (49%) of all these observations involved discussions of general conflict between the wife and husband. Some conflict over domestic roles and finances was discussed by the magazine writers, but few distinct patterns emerge with respect to other specific situations of marital conflict. In fact, we were impressed by the variety of alleged causes for marital troubles (lack of communication, drinking, finances, personality conflicts, in-law problems, extramarital affairs) and the similarity of these themes to contemporary complaints and explanations of marital disruption.¹⁴ The difference between discussions of overt conflict (N=102) and covert conflict (N=57) in husband-wife relationships could suggest that marital tensions were brought out into the open during this period. Since the majority of these discussions (72%) came from fiction, however, this interpretation should be viewed cautiously.

Nevertheless, the literary concern with conflict would seem to reflect certain telling anxieties about the quality of marriage and family life in the mid-nineteenth century. The rhetorical question posed by the editor of the *Continental Monthly* (May, 1864:23) typified this concern: "Do any of you who may be our readers know half a dozen happy families in your circle of friends?" A writer in the *Boston Quarterly Review* (October 1859:492) took the matter even more seriously: "The family, in its old sense, is disappearing from our land, and not only our free institutions are threatened, but the very existence of our society is endangered." Magazine literature during the 1850-1865 period began to expose problems in marriage and family life which previously had been confined to the privacy and secrecy of the home. In this respect, recognition of marital and family conflict may have had the effect of generalizing the nature of the problem and weakening the sense of personal guilt about marital incompatibility.

¹⁴ In many ways, the sources of conflict noted in nineteenth-century magazine literature bear a remarkable resemblance to the complaints of modern divorced women reported by Goode (1956:ch 10).

Table 4. Various Dimensions of the Romantic Love Complex and Character of Discussion (Poetry, Other Fiction and Nonfiction) during 1850-1865 (in Number of Discussions)

	1850-1865			
	Poetry	Other Fiction	Nonfiction	Total
Idealization of the loved one	303	161	16	480 (40%)
The one and only	144	162	7	313 (26%)
Love at first sight	15	60	4	79 (6%)
Love wins out over all	24	153	1	178 (15%)
Glorification of personal emotions	110	47	2	159 (13%)
	N=596	583	30	1209 (100%)

*The Romantic Love Complex:
A Comparison of Periods*

We now shift our focus to another dimension of the relationship between the sexes during the 1850-1865 period. As in our earlier studies, romantic love was defined in terms of five dimensions: (1) idealization of the loved one, (2) the one and only, (3) love at first sight, (4) love wins out over all and (5) glorification of personal emotions. The results of our analysis for 1850-1865 are presented in Table 4.

While discussions of romantic love were quite common in the magazine literature during this period, they appeared somewhat less frequently than in the previous periods. For the two earlier periods, we recorded 337 discussions of romantic love in the 1741-1794 period, or about one discussion for every 1.6 issues and 761 romantic love discussions in the 1794-1825 period, or about one discussion for every 3.1 issues examined. For the 1825-1850 years, we recorded 2,261 discussions of romantic love; this is equivalent to one discussion for every 2.4 issues. In the latter period from 1850 to 1865, 1,209 discussions were observed, or about one discussion for every 5.4 issues. A similar decline of interest in romantic love also has been documented by Hall (1976), who undertook a content analysis of novels, and by Hendrix and Peters (1976), who examined nineteenth-century ballads.¹⁵ The waning preoccupation with romantic

love in the periodical literature would also correspond with the gradual transition from romantic idealism to realism in American literature. As literary critics began to plead for more " 'veritable and veracious' " accounts of " 'the way life really is,' " the emotional sentimentality of earlier periods may have become less appealing (Stovall, 1967)

*Motivations for Marriage:
A Comparison of Periods*

As in the previous articles, three motivations for marriage were considered: happiness, wealth and status. We also noted whether these motivations were held by the individuals entering marriage or by their parents. The data for the 1850-1865 period are presented in Table 5.

Although we recorded 344 discussions concerning various motives for marriage during this period (about one discussion for every 19 issues examined), there was a considerable decrease from the prior period when 1,315 such discussions were found (about one discussion for every four issues examined). This finding would seem to confirm our earlier observation that the magazine literature from 1850-1865 reflected a growing concern with problems of marital and family life (power and conflict) rather than more peripheral, sentimental issues (reasons for getting married and romantic love).

While a general decline in discussions of marital motives is evident, the magazine data are otherwise consistent with previous findings which indicate a strong emphasis on happiness as the predominant motive. Of the total number of discussions, 81% showed this prevailing

¹⁵ Detailed information on these studies is available by writing to Stephen Hall, Department of Sociology, Appalachian State University, Boone, North Carolina or Lew Hendrix, Department of Sociology, Southern Illinois University, Carbondale, Illinois.

Table 5. Marital Motive and Holder of Motive by Character of Discussion (Fiction and Nonfiction) during 1850-1865 (in Number of Discussions)

1850-1865							
Motive	Fiction			Nonfiction			Total
	Parent	Ego	Not Specified	Parent	Ego	Not Specified	
Happiness	9	177	88	0	3	3	280 (81%)
Wealth	10	28	4	0	2	0	44 (13%)
Status	6	4	7	2	1	0	20 (6%)
	N=25	209	99	2	6	3	344 (100%)

concern, while 13% indicated wealth and only 6% indicated status. Parental desires were occasionally considered, but the most common motivation was personal happiness. This finding would indicate an important index of individualism on the part of persons entering marriage—with marriage being primarily a matter of personal choice and happiness. Parental interests were not only less important for the most part, but tended to reflect a more traditional view of marriage as a family affair—a means for acquiring or transmitting property, wealth and status through the family line.

Table 6 provides the data from our content analysis of motivations for marriage for all the periods we have examined. As noted earlier, happiness on the part of ego has accounted for a large proportion of the discussions in each period. Relative to economic and utilitarian motivations, the emphasis on personal happiness is especially significant in the final two periods. A comparison of the distributions of parent and ego motives provides evidence for generational differences in all four studies. Although personal happiness has been the most common topic with regard to the person entering marriage, wealth and happiness have accounted for most of the discussions of parental motives; but the pattern varies considerably from one time period to another.

Perhaps the most noteworthy trend in these data concerns the proportionate decline of discussions of parental desires during the final two periods. In our first two studies, 44% and 33% of the discussions were concerned with parental motives regarding the marriage of their children. In the last two periods, only 8% of the discussions examined from 1825-

1850 and 11% of the discussions in the final period treated the parents' considerations.¹⁶ These literary findings suggest important changes in the basis of marriage as well as in the role which parents and marriage partners played in the process of mate selection. One finds that from 1741 to 1865, we have moved to a position in which the motives of the couple assume more importance in relation to the influences which parents may have had. These findings lend additional credence to the basic family changes which we have previously examined.

Sexual Standards

The magazine content also was examined for evidence regarding the normative sexual structure of the period. Since there were few direct references to the sexual mores, we employed indirect indices in the form of sanctions invoked in premarital or extramarital relations. The three categories of sanctions were punishment, ostracism and sympathy. We also distinguished between those discussions which indicated that a particular sanction *should be* implemented toward a person and discussions in which a particular sanction *actually was* implemented toward an individual. Hence, the three forms of sanctions were classified into one of two categories—attitudes or behavior.

While love, marriage and family problems were important themes of discussion and controversy in the magazine literature of the 1850-1865 period, we found relatively few discussions of sexual sanctions,

¹⁶ These percentages are not presented in the tables, but they can be easily calculated from the data presented in Table 6.

Table 6. Marital Motive (Happiness, Wealth or Status) and Holder of Motive (Ego or Parent) by Time Periods (in Number and Percentage of Discussions)

Ego's Motive	Time Period			
	1741-1794	1794-1825	1825-1850	1850-1865
Happiness	57 (76%)	5 (45.5%)	1112 (92%)	180 (84%)
Wealth	15 (20%)	5 (45.5%)	75 (6%)	30 (14%)
Status	3 (4%)	1 (9%)	17 (2%)	5 (2%)
	N=75 (100%)	11 (100%)	1204 (100%)	215 (100%)

Parent's Motive	Time Period			
	1741-1794	1794-1825	1825-1850	1850-1865
Happiness	17 (29%)	2 (40%)	52 (51%)	9 (33%)
Wealth	30 (51%)	3 (60%)	28 (27%)	10 (37%)
Status	12 (20%)	0 (0%)	22 (22%)	8 (30%)
	N=59 (100%)	5 (100%)	102 (100%)	27 (100%)

sexual deviance or sexual behavior. There were only 41 discussions of the various sanctions either advocated or implemented against persons engaged in sexual misconduct.¹⁷

Perhaps the most important finding for the 1850-1865 period involves the discrepancy between sanctions against male and female sexual deviance. Practically all the discussions in the male categories involved punishment or ostracism, while sympathy was the most frequent response to sexual deviance on the part of the female. This finding can be best understood within the framework of nineteenth-century notions of sexual morality. Walters (1974) and many other commentators have shown that the Victorian lady was exalted for her chastity virtue and innocence. Mid-century males, on the other hand, were constantly advised to keep vigilance over their fierce passions, animal instincts and destructive impulses.

A second observation about the data from our content analysis deserves elaboration. There appears to be a rather sharp discrepancy between attitudes (discussions that sanctions should be implemented) and real behavior (discussions

of the actual implementation of sexual sanctions). In general, the attitudes expressed by the magazine writers tended to be more liberal than the discussions describing the actual enforcement of sexual sanctions. To the extent that these limited findings reflect changing ideas about sexual deviance in the nineteenth century, they may provide an important background for the revolution in sexual behavior during the twentieth century.

In comparison with magazine literature of the eighteenth century, the data for 1850-1865 continue to reflect a lack of literary discussion of sexual sanctions in the nineteenth century. For the first period investigated, we recorded about one discussion for every four issues in the 1741-1794 period and found considerable literary evidence to document the existence of the double standard. After 1794, however, such discussions have become much less common. In the 1850-1865 period, for example, there was approximately one discussion for every 160 issues.¹⁸ It is difficult to determine the attitudes toward sexual deviance solely on the basis of an examination of popular magazines. The general tendency to avoid discussions of sex during these years may indicate that this period was characterized by change and confusion for both sexes. Schlesinger (1966:32), for example, suggests that men were too preoccupied

¹⁷ We recorded one discussion of sexual sanctions for approximately every 160 issues examined in the 1850-1865 period. In comparison with other topics such as power, conflict and romantic love, discussions of sexual behavior and attitudes toward sexual deviance were difficult to find in the magazine literature.

¹⁸ The discussions of sexual sanctions were so infrequent during the 1850-1865 period that we have not included the tabular presentation of findings.

with economic success to devote much time to passion. Women were entering a period in which reason and intellect were valued. Schlesinger maintains that these factors resulted in prudishness about sex, as well as considerable frustration for both sexes. This issue remains an important one for further investigation.

Discussion

The content analysis of magazines from 1741 through 1865 suggests that certain aspects of the family may have been undergoing change. While we recognized that the inability to include some magazines of the 1850–1865 period represented a problem, independent studies by Hall (1976) and Hendrix and Peters (1976) generally confirm the observations we shall make. These studies suggest that traditional male and female roles (especially in regard to the expression and allocation of power) were far more complicated than our own time-bound stereotypes of early American family structure would lead us to believe. Equally important, however, is the realization that ideas about the man-woman relationship may have been undergoing steady modification during the preindustrial period. While the dislocation and blurring of roles was probably intensified as social and technological changes accelerated, the transition in everyday marriage and family life probably occurred over a relatively long period of time.

If we reexamine each of the previous studies, we can observe a pattern that may be relevant. The magazine content in each period suggests changes in the distribution of power, in motivations for marriage, in the importance of romantic love and in attitudes toward sexual deviance. However, the relationship of each variable to the others appears to undergo change, with the distribution of power emerging as the variable of greatest concern in our final period, 1850–1865. If magazine content was an accurate reflection of family change, one might postulate that the process of family change proceeded first in those areas least antagonistic to the power structure of the traditional family. There is no evidence of major at-

tacks on the structure of the family in magazine content in earlier periods. Instead, we find important but lesser changes in the dimensions that we have examined. Yet, nowhere in any of the previous periods studied is there any evidence for drastic efforts to change the family such as those that appeared in the 1850–1865 period. This could mean, first, that earlier family changes set the stage for significant family change in the 1850–1865 period. Second, the data suggest that all the important variables necessary for basis family change in family power structure were not present prior to the 1850–1865 period.

If one accepts that these magazines reflected changes, then it is necessary to explain why these changes occurred. Invariably the linkage between broad macroscopic events and change in social structures is undeveloped. Moreover, the independent and dependent variables in social analysis involving lengthy periods of time do not relate in the same way to one another. Thus, the family, in order to change, can be viewed at one point in time as dependent on external change agents; yet at another point in time, the family can be seen to be an initiator of change that influences external events. The problem is compounded further by the fact that external change agents can differ in their relationships to each other over time. At one point, industrialization may have been responsible for the development of particular ideologies; at another point, ideologies may have had an impact on industrialization. There are at least three major variables that seem to have a bearing on American family changes during the period of our studies—the family structure itself, social ideology and economic development, especially urbanization and industrialization.

The Family

Social structures like the family are capable of changing themselves because they contain some provision for the introduction of new perspectives and values. No single type of family structure can solve permanently the problems which emerge from a given family structure. The

structure of the family at any given point in time achieves some goals at the expense of other possible goals. For example, a patriarchal family of the type we believe existed in America in 1741 achieved integration through an unequal distribution of power. Hence, this patriarchal family carried within it potential ingredients for dissatisfaction among family members; the result was a challenge to patriarchal authority. This challenge, as revealed in our data, took the form of a pattern of subtle female power in particular areas of family life, mutual sharing of power and, in time, even overt power on the part of the female. Such efforts to produce change are not unusual from a sociological perspective. No social structure with a markedly disproportionate distribution of power is devoid of efforts on the part of those without power to change such an arrangement. Such was the case even under traditional caste systems when external ideologies and influences were at a minimum.

Similarly, the goal of imposing a utilitarian, materialistic basis for mate selection may be accomplished at the expense of minimizing the significance of romantic love. Parental domination of mate choice is achieved by negating individual choice. The data for all of our studies suggest that adaptations were probably made by family members in order to cope with the unequal distribution of power. Efforts were made to assert the right of individuals to choose marriage partners for themselves. This dialectical tension in family structure—the imbalance it may create and the alternative ways of dealing with such an imbalance—is an important and neglected component of family change. Nevertheless, internal family variables are insufficient to account for family change.

The Role of External Sources of Family Change

The relationship of a developing economy to family change can be specified conceptually as follows. Traditional family structures encounter difficulties in remaining static in a society in

which the economy is developing because such development creates opportunities for people to introduce change from the outside. Throughout the period of our investigation, the American economy continued to grow and expand—initially through agriculture, trade and commerce. Family change was probably facilitated during America's agricultural phase by the availability of cheap, rich land on the frontier. Young married people who migrated could develop their own patterns of family life without the constraints of their elders. Often the nature of the hardships necessitated a restructuring of traditional family roles. Moreover, frontier areas, with their disproportionate sex ratio favoring women, often created opportunities for the redistribution of roles and power.

In the nineteenth century, the economy began to shift from an agricultural to an industrial base. By 1865, an urban-industrial complex was well underway. This resulted in the rapid growth of cities, an unprecedented need for labor, and freedom from traditional role constraints.

The success of the American economy could have been important in affecting family change in yet another way. One of the reasons family structures in underdeveloped economies change very slowly is that existence is precarious. Thus, people may come to believe that their existing family structure is the only one which facilitates survival. Under these circumstances, change in family structure can be perceived as a threat to the family's capacity to survive. Once a society reaches a stage of economic development where its main concerns are not tied solely to economic survival, and an economic surplus is possible, changes in family structure can be considered. Families then may be more readily able to accept alternative structural arrangements, either those which are generated from within or those from without. The perceptions and energies of people associated with old arrangements can be redirected toward new possibilities. The expansion of the American economy, and the opportunities it provided, made it possible for the family to face the development of new patterns

of family life and could well have facilitated and hastened the possibilities for change.

The Role of Ideology

The development of ideological issues which could have a bearing on changes in family structure have their origins in two major sources. The eighteenth century was a period of considerable political and religious ferment in America. Conventional political structures in the form of English control of the colonies and conventional religious structures and authority came under widespread attack. New trends representing a concern for social justice continued into the nineteenth century in the form of the issue and women's rights.

By the late 1840s, the women's movement became more radicalized, addressing itself not only to the lesser issues of dress and temperance, but also to basic questions about the entrapment of women into the roles of wives and mothers. According to Duberman (1975:11), the efforts of women on behalf of blacks resulted in questions about their own role in society since women often became activists on behalf of minorities, and this kind of activity made women more conscious of their own lowly status.

The second major source of change in ideology arose from the contradiction of wealth and poverty in an economically successful society. The pursuit of materialism was identified as creating false values, and ideological issues arose. The emergence of the utopian community, especially the reform communities prominent in the 1850-1865 period, represented an effort to deal with these concerns. As Muncy (1973:6-7) indicates, the utopian reform communities, which reflected a strong element of socialism, represented a disenchantment with the American family. Reformists believed that family life, at the time, was destructive to personal and social development and was too competitive, beset by rivalries and jealousies. They saw the economy as playing an important role and believed that an economic change could result in a change in

the structure and organization of the family and in the fulfillment of the self and the human personality. These utopian communities could develop in America at this time because the climate of concern for matters of social justice for all groups who felt underprivileged was already present in America. While the communities themselves may have had little lasting impact on the direction of family change, they did help to emphasize certain major ideological themes associated with the search for social justice (political and economic) and for human rights for all groups. However diverted from these principles American society became from time to time, these themes were recurrent. While we have conceptualized a possible relationship between ideology and family change, we cannot delineate or specify the conditions under which ideology resulted in family change, nor do we have data which bears on this question. It is, however, important to speculate on the implications.

We have explored the role of the family as an agent of change itself and we have dealt with the economy, including industrialization and urbanization, and ideology. Nevertheless, while change variables from the family, from ideology and from an agricultural economy were present from the beginning, urbanization and industrialization, both aspects of economic development, did not develop fully in America until much later (Lantz et al., 1975).

An important problem that remains is whether any statements about causal relations can be made. Clearly, the family in America was in a condition of change from the very first, and such change was part of a greater process of change that started much earlier in Europe. Humanistic ideologies, the growth of cities, and development of industry all undoubtedly played a part in such change at different times.

An examination of the European experience would lead one to believe that, from the standpoint of family change, humanistic ideologies were followed by the economic developmental variables of urbanization and industrialization. It is reasonable to assume that some European

immigrants who came to America had already undergone preparation for family change, a change that would result in questioning patterns of authority, the basis of mate selection and motivations for marriage. Efforts to pursue such change continued to emerge in a context of support from America's own preoccupation with the questioning of traditional structures in religion, in government and in relations between people.

Nevertheless, it is doubtful that family change could have developed in America at the speed it did without significant economic development, including both industrialization and urbanization. While virtually every modern characteristic of the family and every contemporary pattern of the man-woman relationship can be found in a limited way in America's past, the data in these studies indicate that the speed at which America became urbanized and industrialized hastened the process of family change, although the process had begun much earlier. This fact should not diminish the role of other variables. For while the causal connection between the several variables influencing family change remains unclear, it is an oversimplification to attribute such change to the consequences of urbanization and industrialization without important qualifications. Such qualifications may involve a recognition of a wide range of social processes whose relationship to urbanization and industrialization is still ambiguous.

Limitations

There are several basic limitations to all of our studies. Although we have discussed the variables which bear a relationship to family change, we have been unable to explain satisfactorily how the family deals with the internal and external variables that tend to create such change. We have merely suggested a process that may be relevant. The problems of using literary sources, such as magazines, remain. There is the problem of accounting for editorial bias in the selection of material. We have tried to account for some of the potential biases, but we cannot be certain that this was accomplished satisfac-

torily. A crucial and unresolved problem with the use of the magazine in history is the problem of understanding the motivations of authors writing about the family. The fact that, in our research, we coded only explicit discussions in magazines, avoiding the implicit meaning of discussions, makes it difficult to deal with the motivations or intentions of authors.¹⁹ Nevertheless, even if one grants the possibility that the picture of female power, especially in the 1850-1865 period, was somewhat exaggerated by authors, it is important to ask why it was exaggerated. One reasonable conclusion is that magazine writers were concerned about female discontent, about power changes already taking place in man-woman relationships and about efforts to seek further changes.

There is always the general problem of ascertaining whether the concerns and contents of magazines corresponded to the real behavior of people. This problem is similar to any sociological effort that tries to ascertain the relationship between the concerns of people as they may be expressed in surveys and their actual behavior. We deal with probabilities. Magazines in each period have been described as increasingly more reliable as an index of public opinion (Tebbel, 1969:ch. 3). Thus, examining the magazine data from all of our studies, 1741-1865, and comparing these results with any other set of social indicators, it becomes apparent that magazines have reflected changes in the American family—changes which have emerged much more fully in the twentieth century.

This picture seemed to emerge initially in an essentially subtle form with a minimum of dramatic content. Thus, for many decades beginning in 1741, fiction and nonfiction magazine content reported preoccupations of people, which appeared to reflect general family change. As we moved into the 1850-1865 period, the issues of family change in magazine content were not only more pronounced

¹⁹ See Welter (1966) for a discussion which attempts to unravel the implicit meanings and hidden motivations of nineteenth-century writers with regard to the "cult of true womanhood."

but also were concerned with the broader issue of improving the position of all those who found themselves under unjust constraints—whether it was women in or out of the family, youths or blacks suffering under slavery. It is therefore appropriate to examine the possibility that literary sources, such as magazines, reflected the early signs of family change in America and may also have been instrumental in fostering that change. If this interpretation is correct, magazine content may be a neglected research tool for those involved in the socio-historic examination of institutions.

Finally, the subject of our investigation from 1741–1865, the reexamination of social institutions (i.e., the family) in historic perspective, is not simply an esthetic exercise that enhances the intellectual content and depth of sociology. It is, perhaps, the most appropriate way in which we can study the process of institutional change in order to increase our capacity to develop generalizations that will stand the test of time.

THE AMERICAN PERCEPTION OF CLASS AND STATUS*

REEVE VANNEMAN AND FRED C. PAMPEL

University of Illinois, Urbana

American Sociological Review 1977, Vol. 42 (June):422-437

Most American sociological research has conceptualized the occupational structure as a continuous prestige hierarchy. The research reported here questions the generality of that conceptualization by examining the relative importance of manual-nonmanual class differences and prestige differences for several attitudes and behaviors. First, the perception of "working class" and "middle class" more closely reflects a manual-nonmanual dichotomy than a continuous prestige scale. Voting behavior and party identification are also better predicted by the dichotomy. Second, the relevance of bounded class and continuous status models varies according to the issues involved. Thus, some interpersonal behaviors and individual satisfactions are patterned according to continuous prestige rankings while opinions on societal issues reflect dichotomous class differences. Third, individuals vary in their propensity to use class or status models according to social structural influences. For instance, a prestige orientation is fostered by small, traditional industries while the class dichotomy is more important in large, bureaucratic industries. The evidence also indicates that occupational prestige is more a middle-class concern, with little importance for manual workers.

Most recent quantitative research on stratification has been based on a status continuum model of the stratification system which assumes a graded hierarchy of occupational prestige (or secondarily, income and education). According to this view, American society is classless because no large cleavages can be found which separate the population into homogenous class groups. The 1947 North-Hatt prestige studies (Reiss et al., 1961) implicitly assume a continuous hierarchy¹ and the replication by Hodge et al. (1966) and Siegel (1971) makes this assumption more explicit:

The cleavage between white-collar, blue-collar, and farm occupations—if it exists at all—is based not so much upon matters of

societal evaluation as perhaps upon the character of dress and work in the three groups. (Hodge et al., 1966:327)

The widespread use of the Duncan SEI and the NORC occupational prestige scales has reinforced the implicit acceptance of the status continuum model.

A second type of model, less accepted by American sociologists, emphasizes distinct and bounded social classes. These classes may be defined by status groups (Warner, 1949), conflict groups with opposed interests (Marx, 1951) or a manual-nonmanual barrier to mobility (Blau and Duncan, 1967). Although status differences exist within or between these classes, the critical difference is the categorical nature of the class concept.² Class dichotomies are intended as more than crude approximations of the status hierarchy; they have an independent sub-

*We wish to acknowledge the work of Lynn Cannon who was responsible for creating the combined four-survey data file and completing the first analysis of the political variables. We would also like to thank Marcus Felson, William Form and Joan Huber for many helpful comments. Support for this research was provided by a grant from the National Science Foundation (74-20753) and the Research Board of the Graduate College of the University of Illinois, Urbana. Data were provided by the Inter-University Consortium for Political Research and the National Data Program for the Social Sciences.

¹ Hatt (1950) did emphasize discontinuous status as an important variable, but considered occupations to be ranked continuously within each status.

² For convenience, we will sometimes refer to bounded models as class models while presenting no evidence concerning market situations or relationships to the means of production. Similarly we will sometimes call continuous rankings "status models," despite legitimate noncontinuous status distinctions which are not continuous (e.g., ethnic groups, Warner's status groups). This should cause no confusion in this paper since we will be contrasting a status model which is continuous (occupational prestige) with a discontinuous class model (the manual-nonmanual gap).

stantive meaning not captured by the continuous scales.

The perception of the stratification system by the general population is often assumed to be based on a continuous model. This is implicit in Hodge and Treiman's (1968) use of the class-identification question and explicit in Lenski's (1952) study of status perceptions in a small community. This is in contrast to work by European sociologists (e.g., Goldthorpe et al., 1969; Popitz et al., 1969) who have sought to describe the class models held by their samples. We will begin with a reassessment of the importance of bounded classes in perceptions of the American stratification system and then extend this analysis to other types of attitudes and behaviors. We will show that, in appropriate circumstances, a wide variety of perceptions, attitudes and behaviors are organized around class divisions rather than along a continuous status hierarchy.

It is necessary to specify the different conditions under which class and continuous models arise. Situational determinants of class and status models have been ignored because of the incorrect assumption that these models are invariant properties of the individual. Moreover, cognitive models vary across individuals in different social positions as well as within a single individual across situational contexts. Certain types of behavior lend themselves more appropriately to one or the other model and certain situations encourage one or the other pattern. Research ought to be directed toward defining these influences rather than championing a given model.

CONDITIONS FOR CLASS PERCEPTIONS

First, position in the social structure influences class and status perceptions. Class and status models have ideological implications that make them attractive to different parts of society. Individual mobility within a social structure suggests a continuous ranking model of society; conflict between opposed groups depends on class perceptions. The continuous hierarchy is, therefore, a middle-class model, consistent with the belief that persons move along the continuum through

individual effort. This image justifies the position of the successful (Mannheim, 1936; Ossowski, 1963). However, the prestige differences that are important to the middle class may have little significance for the working class. Subordinant groups are more likely to hold a dichotomous class image in which society is structured to prevent the lower class from rising to the position of the dominant class. In essence, this is a "them against us" view. Huber and Form (1973) found income in a small American city related to these types of models, and several non-American studies also have found differences in class images based on position in the social structure (e.g., Hiller, 1975).

Second, class models should develop where bureaucratic definitions of formal roles make explicit the social structure of the organization. Less standardized organizational structures should promote more informal patterns of interaction that would blur sharp class divisions. For example, manual workers in process technology have more interaction with technicians and engineers and a more egalitarian and consultative style of interaction than the assembly line worker (Blauner, 1964; Woodward, 1965). The continuous model also may predominate in the service sector. The differences between tailors, policemen, hospital orderlies and library assistants are based more on status gradations than on sharp distinctions in class position. Service work may foster more heterogeneous contacts on the job, contacts which may reduce class consciousness (Hodge and Treiman, 1968; Jackman and Jackman, 1973). Thus, certain technologies (manufacturing rather than service, mass production rather than continuous process) tend to emphasize the distinctions between bounded classes as opposed to rankings along a status continuum. By looking at the relative incidence of discrete and continuous models in different industries, the role of technology in determining class and status perceptions can be evaluated.

Third, the two models are not mutually exclusive in any psychological sense. An individual is likely to have several models; class models may be relevant in some contexts and continuous models in others.

Following Weber, we suggest that responses to societal issues tend to be structured along class divisions but differences in individual life styles are more often distributed along a status continuum. Perceptions of class and society, voting, and political behavior are examples of issues that are societal in focus and are therefore organized more by class divisions. However, individual life styles are typically status concerns and thus more susceptible to continuous rankings. On these issues, class divisions should be less apparent.

STATUS CONTINUUM RESEARCH

The conditions for perception of society as a continuous hierarchy or as discrete classes can be studied empirically with existing data. Unfortunately, much past research has assumed one of the models *a priori*, and those few studies which did attempt to test the models are methodologically inadequate.

The occupational prestige studies (Reiss et al., 1961; Hodge et al., 1966) found a status overlap between lower-white-collar and skilled blue-collar occupations that is sometimes interpreted as evidence against a class model of society (Duncan, 1966; Glenn, 1975). However, the existence of an overlap on this particular task of a synthetic rating of "general standing" does not indicate that a manual-nonmanual distinction is unimportant in all contexts. Duncan (1961) has recommended a direct empirical comparison of the dichotomy with the more continuous scales as a test of their relative importance. Yet, in all the studies of the importance of occupational prestige, this simple statistical comparison has rarely been made. Duncan's own analysis (1966) as well as Glenn's (1975) more recent work did compare the manual-nonmanual dichotomy with income and education as determinants of occupational prestige and found the dichotomy to be unimportant. However, the prestige scale itself has not been compared with the dichotomy in predicting other behavior and attitudes.

Other research, from a different background, has claimed to support the status continuum model. For instance, Lenski (1952) evaluated the Warner scheme of

status groups by asking informants to divide a sample of 173 families into groups according to their "social standing." He found no consensus about the number or size of these status groups. The respondents also were willing to further subdivide the categories they had developed—a willingness Lenski interpreted as evidence of the arbitrary character of any categorical scheme.

Laumann (1966) tried to uncover "subjective class boundaries" through statistical analysis of survey results. Using measures of perceived social distance, Laumann tested for the statistical significance ($p < .05$) of the distance between any two occupations. He found at least three such points that might be interpreted as evidence of class boundaries. Overall, however, the final ranking of the occupations in the Laumann research fits a status continuum model quite closely.

These various empirical efforts raise a number of conceptual and methodological issues. None of the methods yet attempted have been equal to the task of deciding between a bounded class or status continuum model. The following issues must be addressed before any satisfactory resolution can be made.

1. The search for gaps in a status hierarchy is misdirected as a method for detecting class boundaries. First, it confuses two alternative approaches to stratification. Classes are not merely positions along a status hierarchy, but are an entirely distinct phenomenon that must be defined independently (Dahrendorf, 1959:76). Second, the attempt can always be foiled empirically by the inclusion of some interstitial occupation or by the division of an occupation into distinctive subfields. The most foolish of these attempts is a search for statistically significant gaps, since the significance level depends as much on the size of the sample as on the size of the gap. But the basic flaw in this research has been the attempt to develop categories from a unidimensional scale that is inherently continuous, such as income (Hamilton, 1966), social distance (Laumann, 1966), attitudes (Glenn and Alston, 1968) or status perceptions (Hamblin, 1974). Categorical concepts should be categorically defined.

2. Research supporting continuous or discrete models in one analysis cannot be generalized to all perceptions and behaviors. As we argued earlier, the models are not invariant characteristics of individuals. The context of the interview and the wording of the questions will influence the salience of the models. For instance, a request to distribute occupations into five ranked levels of "general standing" may elicit a status model while a request to label them as working or middle class may elicit a class model.

3. The existence of class models does not depend on respondents' ability to spontaneously describe the model as sociologists would (Gross, 1953; Gordon, 1958; Lopreato and Hazelrigg, 1972). It has long been accepted that rules which people cannot verbalize directly influence behavior. Speech, for instance, follows regular rules long before a person can verbalize the rules of grammar. The recent advances in cognitive psychology largely have been the result of use of techniques to uncover these implicit models and rules. While our research uses a more conventional approach, it follows the same strategy of abstracting general rules from respondents' judgments of concrete cases. Other empirical work which has required respondents to explain spontaneously their models of social structure (e.g., Goldthorpe et al., 1969; Popitz et al., 1969; Lopreato and Hazelrigg, 1972; Hiller, 1975) is less promising.

4. Lack of consensus within a community about the boundaries of classes does not imply that individuals hold continuous models. Each may have a somewhat different model which, if aggregated across individuals, may appear to the analyst as a continuous model. While such lack of consensus might imply a low potential for class conflict, it should not be interpreted as evidence for a continuous model as Lenski claims.

5. Finally, respondents' ability to subdivide categories does not necessarily imply a continuous model. The smaller subdivisions may be seen as distinct groups nested within the larger categories. Marx (1951:49) had just such an image of the social structure—nesting two groups, industrial owners and financiers, within

the capitalist class and both capitalists and the landed aristocracy within the bourgeoisie. The Indian caste system also exemplifies this capacity for dividing each group into smaller segments. Neither the divisibility of all categories nor the hierarchical ranking of the subcategories nullifies the fact that the cognitive model is clearly one of bounded groups. No one could claim that the traditional Indian system was continuous.

CLASS IDENTIFICATION RESEARCH

A detailed analysis of class identification offers several advantages for investigation of class and continuous models. First, the class identification question used by the Michigan Survey Research Center encourages a class model by offering two choices—middle and working class—rather than several levels of social standing. If a class model exists, it ought to be reflected in responses to this question. Second, the judgments are concrete—the individual's own position—and the rules by which people define themselves as working or middle class can be abstracted from the concrete judgments.³

Unfortunately, most recent class identification research has implicitly adopted a continuous status model. Multiple regression studies have confirmed what Centers (1949) first reported—occupation has the strongest effect, followed by income and education (Hodge and Treiman, 1968; D'Souza and Sethi, 1972; Jackman and Jackman, 1973). However, the use of least-squares statistics has encouraged the inclusion of continuous variables as predictors; occupation has been measured by prestige scales and education by years in school. Implicit in this approach is the view that responses to class identification questions are only crude rankings along a status hierarchy. This assumption has been reinforced by a recent revision in the dependent variable (e.g., Hodge and

³ Unfortunately, the process of abstraction requires aggregation across individuals; therefore, the lack of consensus on the class boundary will appear as a continuous model. Thus, the test for the existence of a class model will require consensus within the population.

Treiman, 1968) that divides the middle-class response category into middle and upper-middle ranks.

Another possibility exists. Respondents may react to the working and middle alternatives by using a bounded class model. "Working class" may mean more than low status in a continuous hierarchy; it may imply some categorical attributes that set it off from "middle class." Dalia and Guest (1975) have suggested that most of the independent effect of occupational prestige noted by Hodge and Treiman (1968) and by Jackman and Jackman (1973) is probably due to the white-collar/blue-collar subjective class schism. However, this conclusion was not based on any direct comparison of the occupational prestige scale with the dichotomy. Following Duncan's (1961) suggestion, we need only to include the prestige scale and the class dichotomy in the same regression equations to determine whether class identification reflects continuous or class distinctions. If "middle class" and "working class" signify something more than crude approximations to a status continuum, then a class dichotomy should predict those identifications, over and above what is predicted by the continuous status measures.

The research thus seeks to identify one type of stratification image by investigating why people label themselves as either working or middle class. Are persons middle class because they see themselves as positioned high along a continuous status hierarchy (as Hodge and Treiman, 1968, imply), or is it because they see themselves as belonging to a bounded social group (as Centers, 1949, originally intended)? We seek the causes of this self-identification behavior in the traditional way—by determining the strength of relationships to possible predictors. If respondents mean class and not continuous status by working and middle class, the distribution of those identifications should follow some class distinction. If the meanings of these labels reflect bounded classes, there is at least one class model recognized by this population.

Social structural influences on stratification models can be tested by including interaction terms in the analysis. Dalia

and Guest (1975) discovered a strong interaction between the manual-nonmanual dichotomy and the status measures of education and income. This interaction confirms the Ossowski model, that non-manuals are more status-oriented than manuals. The relative importance of occupational prestige to the two classes has not been tested, however.

METHODS

Research Design

To compare the dichotomous class effects and the continuous status effects, we have undertaken a version of analysis of covariance modified for a dummy dependent variable. Figures 1a – 1d represent possible outcomes of this analysis. All would be consistent with positive zero-order relationships between class identification and both the class and status predictors.

In Figure 1a, the class effect is subsumed by the continuous status measure. In such a case, the manual-nonmanual dichotomy can be interpreted only as a crude approximation to the status variable. In Figure 1b, the reverse is true. The continuous status measure explains nothing beyond the manual-nonmanual dichotomy. In this case, we would be justified in rejecting the interpretation of class identification or the manual-nonmanual dichotomy as merely a crude status ranking. In Figure 1c, both class and status effects can be observed. The slopes of the curves are equal but the manual curve is displaced to the right, indicating a substantially lower probability of middle-class identification at any given level of status. Finally, Figure 1d represents an interaction of the class and status variables in predicting class identification. Here status has an effect on class identification only among nonmanuals. Figure 1d conforms most closely to our predictions, based on Ossowski's observations, that continuous models are predominantly middle-class images of the stratification system.

Next, we hypothesize that the use of class and continuous models will vary according to industrial contexts. The effect of the class dichotomy on subjective iden-

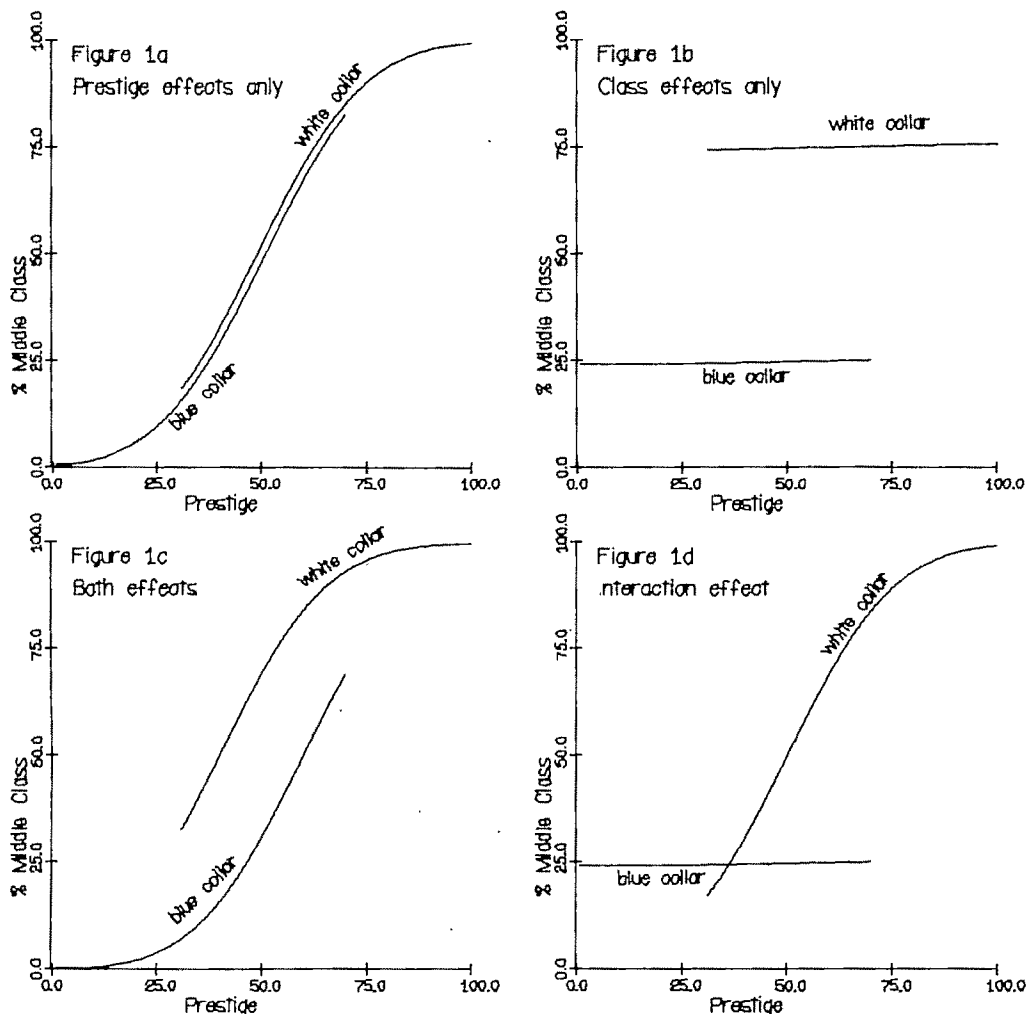

Figure 1. Effects of Class and Prestige on Subjective Identification

tification should be greater for workers in manufacturing than in service, but within manufacturing it should be relatively weak in continuous process industries. On the other hand, the status continua should have stronger effects in service than in manufacturing and be stronger for the process industries. These industrial effects should be explained by the association of class models with bureaucratic organizations.

Finally, we will investigate the scope of class effects by considering a wide range of attitudes and behavior. If subjective identification were the only observable consequence of class divisions in American society, it might be possible to dismiss class divisions as having little signifi-

cance. (Although, even then, we would argue that there was latent potential for class-oriented behavior.) One way to observe class divisions in American society is to examine voting patterns. It is important to note that the chances of observing class differences are not entirely dependent on the psychology of the voters themselves. The American political system is not known for offering clear class choices to the electorate. Thus, while the population may indeed be divided into distinct groups, if the political system does not directly address that division, we would expect little relationship between any class division and voting behavior.

Countless other behaviors and attitudes have been linked to a person's position in

the stratification system. However, no attention has been directed to whether these relationships are due to class distinctions or to variation along a continuous status hierarchy. In particular, we predict that, because of their societal focus, anomia (Srole, 1956) and confidence in national leaders (Roper, 1972) are determined by class differences; but organizational memberships (Goldthorpe et al., 1969; Verba and Nie, 1972), life satisfactions (Campbell and Converse, 1975) and sociability patterns (Goldthorpe et al., 1969) are largely matters of life style that reflect gradations along a continuous prestige scale.

Class and Status Measures

Throughout this paper we will utilize the manual-nonmanual dichotomy to operationalize the bounded class distinction. We recognize that this variable may be only a first approximation to the actual perceived division in American society. Indeed, there is substantial empirical evidence accumulating (Hamilton, 1966; Vanneman, 1977) that the line ought to be drawn to separate the managerial-professional occupations from all others. Further work (McNamee and Vanneman, 1976) explores the nature of the perceived division in greater detail and evaluates in particular the importance of authority (Dahrendorf, 1959) and autonomy (Blauner, 1964). However, we will limit ourselves here to the standard manual-nonmanual distinction because it has the longest research tradition (e.g., Lockwood, 1958) and still has substantial theoretical support (e.g., Giddens, 1973). To the extent we have misidentified the perceived gap, our results would be biased against uncovering class effects.

Occupational prestige was coded according to the most recent rankings reported by Siegel (1971) based on the 1963-1965 replication of the original NORC study. These scores are derived from a direct attempt to measure subjective prestige and, therefore, should represent the best contrast to an objectively defined class distinction.⁴ Education is

scored as years of school completed except that respondents with incomplete college were coded as 14 years, respondents with post high school non-college training as 13 years, and respondents with graduate degrees as 18 years. Income was recoded to the actual dollar value of the midpoint of the survey categories.

Samples

The principal data were collected by the Survey Research Center at the University of Michigan in four, biyearly pre-election interviews, from 1966 to 1972. Respondents were assigned weights so that the sample size for each year equalled the harmonic mean of the four sample sizes. Most of the analyses reported here focus on the white male non-farm labor force. Earlier research (Jackman and Jackman, 1973; Evers, 1975) has found the class identification process for blacks to be substantially different from the process for whites. Only labor force members were included because of the different interpretations given to occupation and even income among the non-labor force. Farmers were excluded because of their ambiguous position in a dichotomous class structure. The largest exclusion, women, was necessitated by the uncertain importance of husband's and own job in determining class identification (Ritter and Hargens, 1975) and evidence, to be presented, that the class identification process is different for women. For the class identification analyses, respondents with missing data (5.6% of the sample) had to be eliminated. This left a main sample of 1,865 respondents, which, after weighting, yielded an effective N of 1728.40.

Data from the 1972, 1973 and 1974 General Social Surveys also were utilized to supplement the main analyses with the SRC data.⁵ Again, the white male non-

using the Duncan SEI instead of the NORC prestige index. The results do not yield different interpretations although, in general, the Duncan SEI does have stronger associations. The results from the SEI are available from the authors.

⁵ These data utilize a four-category response: lower, working, middle and upper. The small lower and upper categories were recoded into the working

farm labor force was the main sample, in this case 1,000 respondents.

Probit Analysis

The objective of much of the statistical analysis is to determine the effects of various stratification measures on class identification. In this case, it would be incorrect to assume linearity between a continuous independent variable and the dichotomous dependent variable throughout the range of the continuous variable. For example, an increase from \$30,000 to \$40,000 in income would not cause the same increase in middle-class identification as would an increase from \$5,000 to \$15,000. More appropriate for the statistical analysis required here is a normal ogive model (Lord and Novick, 1968) in which an increase in status at either end of the hierarchy will have less effect on class identification than an increase in the middle of the hierarchy. The assumptions of the normal ogive are exactly the assumptions implicit in the status hierarchy interpretation of class identification. If class identification were only a dichotomization of self-placement along a continuous status hierarchy, the relationship between a continuous status variable and a dichotomous class identification would follow a normal ogive. But the assumptions of the linear model would "penalize" the continuous linear variables by requiring a uniform slope throughout the range of the status variables. Dichotomous independent variables would not be handicapped in this way and so might appear more powerful in the linear model. Thus, the use of the normal ogive provides a more rigorous test of the importance of class distinctions.

Because of the superiority of the normal ogive model, probit analysis (Goldfeld and Quandt, 1972) will be utilized rather than multiple linear regression. The two methods yield analogous results — the

only difference is that multiple regression tries to fit the data to a straight line while probit analysis seeks a fit to the normal ogive. A maximum likelihood solution is developed through an iterative technique.

CLASS IDENTIFICATION

Figure 2 graphs the observed relationship of occupation on class identification. The individual points were obtained from a sliding average at each prestige level based on all scores two points and less above and below the point being graphed. The smooth curves represent the best normal ogive approximations to the data.

These results demonstrate the importance of the manual-nonmanual distinction after controlling prestige level. Higher prestige blue-collar workers see themselves as substantially more working class than white-collar workers at the same prestige level. These results are confirmed after controls for education and income have been added (Table 1). In the SRC data, the standardized coefficient for the class dichotomy is significant and substantially higher than the prestige coefficient. The effect of the manual-nonmanual dichotomy is equivalent to about 47 points on the prestige scale, or about 3 1/3 standard deviations of prestige. In the GSS data, the prestige coefficient is not statistically significant while the manual-nonmanual gap is still large.

We should emphasize that this result is not an artifact of relating one dummy variable to another, since probit analysis seeks out the optimum point of inflexion in relating the continuous prestige index to the dichotomous dependent variable. This implies that no dichotomization of prestige would yield a better fit than the manual-nonmanual split. In fact, when the best dichotomization, at a score of 49, is substituted for the manual-nonmanual dichotomy, the fit (chi-square = 519.4) is substantially poorer and the coefficient of the dichotomy (.269) is smaller.⁸ Substan-

and middle alternatives in order to provide comparable results. The half-sample in 1973, which presented five possibilities including an upper-middle alternative, was eliminated from the class identification analysis.

⁸ The best prestige dichotomy was determined simply by trying every possible break point. The score of 49 was "best" in the sense that it gave the highest chi-square (and thus the maximum likelihood function). Only 30% of the respondents had prestige scores greater than 49.

Figure 2. Middle-Class Identification by Occupational Prestige

tively, this means that the working-class and middle-class labels reflect the content of the class division, i.e., manual and nonmanual labor, and are not merely prestige judgments.

Table 1 also indicates the importance of education and income in determining class identification.⁷ While their importance would seem to support the continuous status-ranking interpretation, we should note that the education effect is itself close to being discontinuous. Much of the education effect is subsumed under the

⁷ Although in this analysis the occupational effect is divided between two variables, when either variable is dropped, the occupation effect still remains weaker than the education or income effects.

college versus noncollege distinction. Middle class in American society now implies having gone to college; it is not just the extra years of school, but the categorical distinction of being "college educated." The importance of this distinction is evident after the effects of occupation and income are controlled. When the some-college versus noncollege dichotomy is substituted for the continuous years of education, the standardized coefficient of the dichotomy (.329) is close to the coefficient for the continuous variable (.405) reported in Table 1. When a second dummy variable identifying college graduates is added to the equation, the fit is even better than for the equation

with the continuous years of school (chi-square = 545.98).

Table 2 reports the equations fitted for working women and wives of working men. For women's jobs, the manual-nonmanual coefficient is less than twice its standard error and is, in fact, negative. If there is a perceived class division, it is not the manual-nonmanual distinction. Occupational prestige, moreover, is more important for women than for men ($b = .020$ versus $b = .010$). The difference in the class identification process for women is probably a result of the different jobs that women have, rather than evidence of

a different social psychology. Married women's interpretation of their husband's jobs is quite close to the men's results.

Interactions

Figure 2 also suggests that prestige is more important for white-collar workers than for blue-collar workers. This interaction is confirmed when separate analyses are made on manual and nonmanual workers. The occupational prestige coefficient for manual workers (-0.0005) is only a fraction of its standard error and thus may be considered to equal zero. For

Table 2. Middle-Class Identification of Women

blue-collar workers, therefore, the higher prestige of skilled work makes little difference for their subjective identification (although the extra income of this work is important). However, for nonmanuals the prestige coefficient (.0136) is over three times its standard error. Thus, the lower prestige of some of the clerical and sales work does imply a working-class identification — not merely because of the lower income and education associated with these jobs, but because of the lower prestige of the job itself. Similarly, education is almost twice as important for nonmanuals (.1547) as for manuals (.0861), although both coefficients are more than twice their standard errors. Only income has approximately equivalent effects for manuals (.0428) and for nonmanuals (.0440).

INDUSTRIAL CONTEXTS

A close comparison of manufacturing and service contexts fails to support the greater prestige orientation of service work. In the global comparison of workers in service and manufacturing, the prestige coefficient is indeed larger in service (.0136 versus .0012) and the class coefficient slightly smaller (.4051 versus .6389). However, the seemingly large difference in prestige effects can be explained by nonmanual predominance in service industries. We already have noted the greater importance of prestige among such nonmanuals. When the nonmanual-manual interaction is controlled, the difference between manufacturing and service disappears. Prestige has little effect among manuals in either sector (−.017 for manufacturing, .008 for service—both less than twice their standard errors), while among nonmanuals the effect of prestige is even greater for manufacturing (.019) than for service (.013)—exactly the opposite of the prediction.

Education also has roughly equal effects in manufacturing and service sectors (.084 and .090 for manuals, .147 and .147 for nonmanuals). There is thus no evidence to support the greater importance of education for subjective identification

in the “post-industrial” service sector (cf. Bell, 1973).

However, manufacturing and service are themselves heterogeneous categories. A more detailed investigation of industrial contexts was undertaken by dividing the sample into sixteen industry types.⁸ Separate normal ogive equations were fitted for each industry. Several of these coefficients fit our expectations. In particular, process industries have a larger prestige effect (.029) than any other manufacturing industry (e.g., machinery and automotive, .008) and smaller, indeed negative, class effects (−.123 versus .342 for machinery and automotive). Also, the small, less bureaucratized services tend to have larger prestige effects (e.g., personal services, .041) than the large service bureaucracies (e.g., public administration, .016) and smaller class effects (.263 versus .613).

In order to interpret the size of the prestige and class effects in all sixteen industries, the coefficients calculated from the sixteen probit analyses were correlated with other industrial characteristics. The sixteen industries used as units of analyses for these correlations were weighted by the number of respondents in the industry. The results of this analysis (Table 3) are suggestive although hardly conclusive because of the small base of sixteen industry categories as well as the small samples in each industry (average sample = 119) used to calculate the prestige and class coefficients.

The size of the class and prestige effects are moderately related to two indicators of bureaucratization (Stinchcombe, 1965). Class effects are larger and prestige effects are smaller in industries with a large percentage of clerks. Conversely, industries with a high percentage of self-employed workers have small class but large prestige effects. Both of these indicators suggest that in small, traditionally organized enterprises there is not a wide gap between manuals and nonmanuals, although status differences are important. However, in the larger rationalized bureaucracies, workers divide themselves

⁸ The list of industries and data are available from the authors.

* $p < .10$ ($N=16$).

** Correlations weighted by the number of respondents in each of the sixteen industries.

more into two distinct groups, but status differences within these groups are not especially important. Also congruent with this interpretation is the association of urbanized industries with class effects and rural industries with prestige effects.

Education and income effects also vary largely according to the percent of high-status, white-collar workers. Both education and income effects are strongest in bureaucratic industries (i.e., high percent clerical, low percent self-employed). But income effects are positively related to percent white-collar while education effects are negatively related. In high-status industries, income best differentiates middle-class persons from working-class persons. In low-status industries, education best defines middle-class membership.

The evidence for these contextual effects is only indirect since there is no information for each respondent about the size or bureaucratization of his own organization. This type of information would clarify the picture substantially. Nevertheless, the percentages self-employed and clerical have been shown to be quite stable characteristics of individual industries that reflect the age of the industry and the extent of rationalization of the work process.

CLASS-ORIENTED BEHAVIOR AND ATTITUDES

Political Behavior

Data from three presidential elections are included in these surveys. The 1964 election was covered retrospectively in the 1966 and 1968 surveys; the 1968 elec-

tion was covered retrospectively in the 1970 and 1972 surveys in addition to post-election interviews in the 1968 survey. Discriminant function analysis was required since there are three distinct behaviors possible in each election—a Republican vote, a Democratic vote or no vote.

The 1964 and 1968 results are quite similar. In each, only one discriminant function is significant (Table 4). This function is a general dimension of status which ranks Republican voters highest, non-voters lowest and Democratic voters in between. What is important for our purposes is the greater weight of the simple manual-nonmanual dichotomy than the prestige scale. Again, most of the influence due to occupational position is not the result of an individual's location along the prestige hierarchy but his placement in either the manual or nonmanual groupings.

The 1972 election reveals a quite different pattern. Here two separate functions achieve significance. The first predicts non-voting and the second, a McGovern vote. In both functions, the role of the manual-nonmanual dichotomy is weak, which supports the impression that the 1972 election was not fought along these class lines.

Linear regressions on party identification confirm the importance of the class dichotomy for American political behavior. Table 5 reports the standardized coefficients for the four basic indicators utilized throughout this paper as well as for a more complete set utilized in other studies of party identification (Knoke, 1972). In both cases, the standardized coefficient for the occupational dichotomy is much larger than the occu-

pational prestige coefficient. The college versus noncollege dummy is used in these equations since it is a better predictor than the continuous scale ($\beta = .123$ versus $\beta = .086$ for the four-variable model). The results indicate that most political behavior studies have erred in using the more complete continuous scales rather than the simple dichotomies. More important, the theoretical implication is that, even in the United States, political behavior is organized more along class than status lines.

Other Behavior and Attitudes

Five domains of attitudes and behavior were selected from the 1974 General So-

cial Survey to explore further the scope of class and status effects in American society⁹. Each domain was measured by several items in the national survey; therefore, the relationship of each domain to the stratification measures was tested through canonical correlation. The first canonical variate was interpreted as the principal way in which these behaviors were patterned by the stratification system. Table 6 reports the standardized coefficients for the four stratification variables; they are equivalent to standardized beta weights in a regression on a variable defined by a linear combination of the dependent variables.

In comparing the relationships of the manual-nonmanual dichotomy with occupational prestige, the more clearly societal areas—confidence in national institutions and anomia show stronger class relationships and negligible prestige relationships. However, life satisfactions and organizational memberships, areas which reflect interpersonal life styles, show the opposite pattern—prestige relationships without any class relationships. Sociability patterns, contrary to the prediction, do not vary with occupational position.

None of these relationships are noticeably large. We should note, too, the general importance of education and, for life satisfactions, income. Nevertheless, the

important result is that the type of behavior being studied determines, to a large extent, the relative size of the class or prestige relationships. Those attitudes and behaviors that address societal issues are determined more by class than prestige. However, in the realm of personal life styles, prestige is more important than class differences. In this light, it is impossible to say that any given society is strictly class or status oriented since this orientation is a function of the type of behavior.

DISCUSSION

The results suggest that the division in American society between manual and nonmanual workers is more important than previously thought. The division is something more than a status distinction of occupational prestige, education and income. Although there are large status differences within manual and nonmanual groups, there is a perception of common categories—working-class or middle-class. Indeed, if we consider Glenn's (1975) results, we would have to conclude that nonmanual work carries no independent prestige value of its own.

This paper has sought to reorient the debate between continuous and discontinuous models of the stratification system in order to provoke a search for those conditions which encourage one or the other model. In this search, the models become variables themselves rather than invariant properties whose truth or falsity must be established. Some circumstances and issues favor the use of the class model while others favor a continuous model. For example, it appears that status differences are more important to nonmanual workers than to manual workers. In fact,

consistent with other theory (Ossowski, 1963) and research (Huber and Form, 1973), concern for status and the image of society as a continuous status hierarchy of minute gradations are largely middle-class phenomena. Small, rural industries also seem to encourage the prestige models. We suspect that the importance of class and status models also varies cross-nationally. Is American society less sharply divided than European societies? If so, would the more continuous gradation in the U.S. be explained by its higher percentage of nonmanual workers.

Finally, the relative importance of the two models varies not only across individuals but also within individuals across different domains of attitudes and behavior. Although the sample of such attitudes and behaviors included in this study is small, one criterion can be seen in the results. If the issue concerns the structure of the society, the manual-nonmanual division is most important. Politics is the best example of this type. However when the issue has a more individual focus, the continuous status variables best describe the observed differences.

If we admit that class and status models are not invariant properties of individuals, we should rethink the implications of cognitive models for mass social action. Class consciousness does not require the exclusive use of bounded models; rather, it is sufficient that people are able to respond meaningfully in terms of classes in some contexts. Given this, they can be mobilized for class conflict appealing to their class interests. Thus, the search for "spontaneous" images is misdirected. Mass social action does not depend on each person individually constructing an appropriate response. Protest behavior is typically a socially structured alternative

available to people. Their participation does require that the alternative meaningfully fits some image they have of society, but it is not necessary that they use only that image in all contexts. The results of this research demonstrate that bounded class models are meaningful to Americans, especially blue-collar Americans, and that important attitudes and behaviors are organized around class divisions.

MANUSCRIPTS FOR THE ASA ROSE SOCIOLOGY SERIES

Manuscripts (100 to 300 typed pages) are solicited for publication in the *ASA Arnold and Caroline Rose Monograph Series*. The Series welcomes a variety of types of sociological work—qualitative or quantitative empirical studies, and theoretical or methodological treatises. An author should submit three copies of a manuscript for consideration to the Series Editor, Professor Robin M. Williams, Jr., Department of Sociology, Cornell University, Ithaca, New York 14853.

CLASS, STATUS, AND "REACTIVE ETHNIC CLEAVAGES": THE SOCIAL BASES OF POLITICAL REGIONALISM

CHARLES RAGIN

Indiana University

American Sociological Review 1977, Vol. 42 (June):438-450

Two conflicting perspectives on the nature of political regionalism in Britain are examined. The first, based on a developmental perspective, argues that there is a high degree of regional uniformity in party support in Britain. The second, based on the theory of reactive ethnic cleavages, supports the view that Celtic political distinctiveness is a persistent feature of British politics. Both perspectives are found to be inadequate because of errors in conceptualization and design. One such error is the assumption that class affinity and status-group affinity as bases for political action are mutually exclusive orientations. Supporters of both perspectives argue that the predominance of class implies that status affinity is relatively unimportant and vice versa. A serious design defect concerns vote dichotomization; typically, researchers have examined the votes for only a single party. This paper demonstrates that the analysis of Conservative votes supports the theory of reactive ethnic cleavages, while the analysis of Labour votes supports the developmental perspective. Together, these findings support a third argument—that in economically peripheral areas, an appeal to regional or "ethnic" interests by the local dominant strata may be provoked by local class cleavages.

Many researchers have emphasized the uniformity of voting across regions in Britain, with class as the primary homogenizing force (see Alford, 1963:151; Blondel, 1963; Pulzer, 1967:98; Butler and Stokes, 1969:150). Blondel (1963:26), for example, states that class divisions are fundamental in Britain "simply because, elsewhere, local characteristics often unite people of all classes to an extent that is rarely attained in Britain." These authors usually employ a *developmental perspective*. In this perspective, functional, class-based cleavages are thought to supersede status-based cleavages as structural differentiation progresses over time. The clearest statement of this approach is in Lipset and Rokkan's (1967:1-64) introduction to *Party Systems and Voter Alignments*. They construct a complex, developmental typology based on an application of Parsons' A-G-I-L scheme to political cleavages in Western democracies.

The relevance of this perspective to the British case has been challenged recently by a number of researchers. For example, Rose (1974:20-3) argues that, sociologically and politically, Britain is a *multi-national* state. Noting that the Conservative Party is stronger than Labour in Eng-

land, while the reverse is true in Scotland and Wales, he argues that political parties in Britain have *national* as well as class images. Hechter (1975:208-35) cites the anti-Conservatism of Scotland and Wales as support for the *theory of reactive ethnic cleavages*. According to Hechter, the political distinctiveness of Celtic areas in Britain is a product of the internal colonization of these areas (the periphery) by England (the core).¹ One consequence of internal colonization is a "cultural division of labor" (Hechter, 1975:38). This results from the application of particularistic (e.g., cultural) criteria in the allocation of roles and resources. Following Barth (1969) and Gellner (1969), Hechter (1975:39-40) argues that *ethnicity* may arise from the salience of cultural distinctions in the system of economic stratification. This cultural division of labor may occur at any (societal) level of structural differentiation according to the theory of reactive ethnic cleavages (Hechter, 1975:223).

Although these two perspectives are clearly in conflict, both endorse an ana-

¹ For a succinct exposition of the concepts of core (or center) and periphery, see Galtung, 1971:81-117; Wallerstein, 1974:347-57.

lytical distinction between two bases of political action, *class* affinity and *status-group* affinity (see Weber, 1946:180-95). According to the developmental perspective, class cleavages in Britain have *superseded* status-based cleavages, while, according to the theory of reactive ethnic cleavages, the persistence of a status cleavage (Celtic sectionalism) represents the *failure* of class to become predominant. The present article shows that the contradiction between these two arguments is more apparent than real by demonstrating that Celtic sectionalism has roots in both class and status-group affinity.

REFORMULATION AND CRITIQUE

The Relationship between Class and Status-Group Affinity

The developmental perspective and the theory of reactive ethnic cleavages both adhere to Weber's distinction between class and status-group affinity. Both perspectives classify cleavages as class based *or* status based, and both support the notion that class affinity prevails at the expense of status-group affinity and vice versa.

Cohen (1976:1160), however, argues that Weber's discussion of class and status does not support the notion of *mutually exclusive* categories of group orientation. He points out that Weber's distinction between class and status-group affinity is an *ideal typical* contrast. Indeed, Weber (1946:187) argues that status honor "can be knit to a class situation: class distinctions are linked in the most varied ways with status distinctions." In this light, Weber's (1946:190) argument that the "style of life expected for members of a status group is usually conditioned economically" should not be interpreted to mean that economic conditions must eliminate status affinity. Rather, as Cohen (1976:1160) argues, "Weber . . . appears to indicate that the economic circumstances in which class affinity originates *circumscribe* or *condition* the social circumstances in which status affinity originates" (original emphasis).

Class, Status, and Political Regionalism

There are many world-wide examples of core-periphery conflicts occurring within the territorial boundaries of nation-states. In Western democracies, core-periphery conflicts usually gain expression via sectionalism. A pattern of political distinctiveness that is confined to a reasonably well-defined peripheral area is called peripheral sectionalism.²

The analysis of the social bases of peripheral sectionalism is greatly facilitated by a repudiation of the simplistic dichotomous distinction between class and status-group affinity. Since peripheral areas are usually culturally distinct from core areas (that is, these areas are "culturally peripheral"), a status interpretation of peripheral sectionalism is enhanced. However, peripheral areas usually experience specialized economic development (as a consequence of the geographic division of labor—see Wallerstein, 1974:347-57), and the class structures of peripheral areas reflect this specialization. Class factors, then, may condition or limit the growth of peripheral sectionalism.

Linz (1973:69-72), for example, contrasts two peripheral areas in Spain, Catalonia and the Basque Provinces. Historically, the Basques have been united in their opposition to Castilian Spain, while the Catalonians have been divided between two class-based peripheral opposition groups. Linz (1973:69-72) argues that in the Basque country the PNV (Basque separatist party) was able to take a populist stance "appealing to petty bourgeois anti-capitalist sentiments and supporting its own trade union movement" because in the Basque Provinces there are "many small entrepreneurs, highly skilled and paid workers, and well-distributed rural property." In

² Hechter uses the term "peripheral sectionalism" to refer to *culturally*-based sectionalism, but his usage is inappropriate because *periphery* refers to a particular type of area, one that has experienced specialized economic development by a core. Peripheral sectionalism is used in this paper to refer to sectionalism based in these areas of specialized development, without regard to its specific source (i.e., structural versus cultural).

Catalonia, however, a "three-cornered conflict emerged among employers, workers, and [Castilian] national authorities." According to Linz, this class conflict in Catalonia limited the development of peripheral sectionalism.

Regional political tendencies in Norway also reflect differences in economic specialization and in class structure. Rokkan (1967:415) contrasts the different regions of Norway along these two dimensions. His fourfold typology is based on two dichotomies: hierarchical communities versus equalitarian communities and inland economy (agriculture and forestry) versus coastal economy (fishing). There are four possible combinations. Rokkan specifies the political tendencies associated with each type. In some regions, the pattern of political distinctiveness is the product of the highly uniform support of one class for a particular political party; in others, it is more the product of general cross-class support for a particular party.

These examples are suggestive of the great variety of peripheral political responses. They also suggest that class factors are frequently important in the origin and evolution of these responses. This emphasis is very different from the emphases of existing treatments of regional factors in British politics. These arguments are extreme in their emphases, one supporting the idea of regional homogeneity based on class, the other maintaining the failure of class politics in peripheral areas and the consequent persistence of a status-based cleavage.

The Social Bases of Celtic Sectionalism

The specialized economic development of Scotland and Wales has been primarily industrial. This industrialization has led to the creation of a large, industrial working class in the Celtic periphery. Thus, industrial conflict has been more intense in the periphery than elsewhere in Britain (see, e.g., Pelling, 1958; 1968). Wallerstein (1974:353) argues that it is class conflict in peripheral areas that encourages the formation of culturally based, peripheral opposition to core areas:

Geographic concentration of particular economic activities serves as a constant pressure to status-group formation. When the local dominant strata are threatened by the incipient class consciousness of lower strata, emphasis on local culture serves well to deflect local internal conflict, creating instead local solidarity against the outside. If, in addition, these local dominant strata feel themselves oppressed by higher strata of the world system, they are doubly motivated to pursue the creation of local identity.

Obviously, one does not construct an identity out of thin air. One builds on what one finds—in terms of language, religion, and distinctive life-styles. Nonetheless, it is quite clear that both linguistic and religious homogeneity and passion (a fortiori devotion to separate life-styles) are social creations which cannot be accounted for as simple continuities of tradition eternal. They are social creations molded with difficulty in times of travail.

As the contrast between Catalonia and the Basque Provinces clearly illustrates, however, the local dominant strata of a peripheral area may be unsuccessful in creating cross-class solidarity.

Following Wallerstein, one would expect sectionalism in the Celtic periphery to *originate* in the local dominant strata. Following Linz, one would want to ascertain the degree to which this process of status-group formation is limited, if at all, by class cleavages. The fact that the Labour Party is strong in Scotland and Wales suggests that the local dominant strata have not generated local solidarity. Hechter (1975:292), however, argues that the Labour Party has served as one of several *outlets* for Celtic sectionalism. Indeed, he argues that the Labour Party is strong in Scotland and Wales *because* of Celtic sectionalism (1975:264–310). The basic argument of this paper is that (1) the Labour Party has not served as an outlet for Celtic sectionalism and, by implication, (2) the process of status-group formation in Celtic areas has been severely limited by class cleavages.

Review of Existing Analyses of Political Regionalism in Britain

Two contemporary studies of British voters, Butler and Stokes' (1969) *Political*

Change in Britain and Alford's (1963) *Party and Society*, have examined regional variations in voting behavior. Both support the notion that there is a high degree of regional homogeneity in British politics.

Butler and Stokes present data on Britain showing the cross-tabulation of class and political choice for each region. They note a strong, consistent relationship between class and party support in all areas of Britain. This is qualified, however, by a distinction between two areas within Britain, the "depressed north" and the "expanding south" (Butler and Stokes, 1969:142). They find that in the north the working class is much more unanimous in its support of the Labour Party. Noting that the relative size of the working class is also much greater in the north, they hypothesize that class has a contextual effect. Thus, the larger the working class is in an area, the greater the probability that working-class individuals will support the Labour Party. Conversely, the greater the size of the middle class, the greater the probability that middle-class individuals will support the Conservative Party. They demonstrate these arguments with scattergram analyses of the proportion of the working class supporting Labour and the proportion of the constituency which is working-class (Butler and Stokes, 1969:149). They conclude that regional variations are unimportant in Britain once the contextual effect of class is taken into account (Butler and Stokes, 1969:150).

Alford's (1963) analysis of region and class is somewhat different from that of Butler and Stokes, though the conclusions are very similar. Alford concentrates on regions which might have the greatest possibility for a sectional response, Wales and Scotland. (This is very much in contrast with the emphasis of Butler and Stokes [1969:149]; in one scattergram of regions, they exclude Scotland and Wales altogether.) Alford considers the possibility that a reaction in the Celtic periphery to the colonial-like exploitation of the area by the English might pull both classes over to one party. Thus, a united opposition would confront the exploiters. He fails to find such opposition. Alford (1963:144) does find greater support for

the Labour Party in Wales and Scotland, but he also finds higher class voting in these areas. Thus, even though there is strong support for the Labour Party, the *difference* between the percentage of the working class voting Labour and the percentage of the middle class voting Labour is greater in Wales and Scotland than elsewhere according to Alford's analysis. He concludes that there is no evidence of an anti-colonial reaction in Scotland and Wales.

In support of the theory of reactive ethnic cleavages, Hechter examines historical, aggregate data on British counties. He analyzes the determinates of Conservative voting at eight points in time in British political history. The theory of reactive ethnic cleavages argues that there is no necessary relationship between the existence of ethnic boundaries and the degree of complexity of social organization. Thus, it is expected that Celtic differences should persist into the modern period, given the persistence of a cultural division of labour.

Hechter (1975:208-33) regresses county levels of Conservative support against a set of interrelated indicators of industrialization. These indicators include the occupational breakdown of the working population into primary, secondary and tertiary sectors, population indicators such as percentage sixty-five years of age and older and population growth rate, and an indicator of urbanization. He notes that the level of explained variance in Conservative vote by these variables does not increase over time (Hechter, 1975:320). After analyzing total explained variance by these variables at each point in time, Hechter examines the effects of cultural variables associated with Celtic identity, such as level of religious Nonconformity and percentage Welsh- or Gaelic-speaking, on county levels of Conservative support, in an attempt to demonstrate the persistence of cultural factors. Before regressing cultural variables on the Conservative vote, however, Hechter removes the effects of the structural variables from each cultural variable. Thus, Hechter analyzes the importance of "cultural residuals." Regression analysis shows that the cultural residuals consistently explain

as much, if not more, of the variance in Conservative support than the various indicators of industrialization (Hechter, 1975:319). Hechter concludes from his analysis that Celtic peripheral sectionalism has persisted in British politics despite structural differentiation.

Critique

Given that Alford, and Butler and Stokes (developmental perspective) and Hechter (theory of reactive ethnic cleavages) all employ a dichotomous conception of the relationship between status and class, it may seem surprising that their empirical findings are fundamentally different. The contrary findings these researchers report are explained by the fact that each restricted the scope of his analysis. Since World War I, political competition in Britain has been multiparty. Prior to World War I, there were four parties; but the Liberal Unionists were allied with the Conservatives while Labour was allied with the Liberals, thus narrowing competition to two groups. Analysis of political data is relatively uncomplicated if there are only two competitors, since support for one party is perfectly, negatively correlated with support for the other. This is not the case, however, if there are three or more separate parties.

Since there are only two *major* parties in post-World War I Britain, researchers have tended to analyze support as if there were only two parties. Alford, for example, analyzes only Labour versus non-Labour support; that is, he lumps Conservative, Liberal, and Celtic nationalist support into one category. Hechter, on the other hand, analyzes only Conservative support. He combines Labour, Liberal, and Celtic nationalist support together, arguing that each of these parties has served as an outlet for Celtic anti-Conservatism. Butler and Stokes systematically exclude "third parties" by analyzing only proportions of Labour plus Conservative support, thus denying the reality of Liberal Party and Celtic nationalist party supporters in their empirical analysis of regional variations. Hechter (1975:218n) argues that the analysis of Conservative Party support is most suited for the examination of regional variations

since Celtic political responses have been primarily anti-Conservative. Alford (1963:79-86), on the other hand, argues that the Labour-non-Labour split is most appropriate for the examination of class voting.

To gain a complete understanding of political regionalism in Britain, it is necessary to examine separately the social bases of Conservative Party and Labour Party support. The analysis of Labour voting appears to support the developmental perspective, while the analysis of Conservative voting appears to support the theory of reactive ethnic cleavages. Clearly, the only way to adjudicate between these two perspectives, or at least explicate the contradiction between them, is to analyze independently the support for each party.

Hypotheses

If the theory of reactive ethnic cleavages is correct, then cultural factors associated with Celtic identity should have a negative effect on Conservative Party support and a positive effect on Labour Party support. This is consistent with this theory's argument that Celtic sectionalism has been expressed via an anti-Conservative posture, with the Labour Party serving as one of several outlets. If the developmental perspective is correct, cultural factors should have little effect on either party, especially after the rise of Labour as a major national party. This prediction is based on the notion that as the societal level of structural differentiation progresses over time, functional, class-based interests should prevail. If, however, status-group formation in a peripheral area originates among the local dominant strata and is arrested by class cleavages, as the arguments of Wallerstein and Linz suggest, cultural factors associated with Celtic identity should have a negative effect on Conservative support and *no* effect on Labour support.

DATA AND METHOD

Data

The data used in this study are in most respects very similar to those used by

Hechter: county-level, historical census and election data.³ For the sake of comparability, I analyze data on the same elections that Hechter analyzed, the elections of 1885, 1892, 1900, 1910, 1924, 1931, 1951 and 1966. The census data are from the *County Reports* of the *Census of England and Wales* and the *Census of Scotland* for the years 1881, 1891, 1901, 1911, 1921, 1931, 1951 and 1961. The *County Reports* form a special volume in each of the British censuses.

There are 86 counties in Britain; 40 English counties, 13 Welsh counties and 33 Scottish counties. While Celtic areas constitute only about one-seventh of the population of Britain, over one-half of all British counties are Celtic. Regression analysis of the county data is comparable in many respects, therefore, to stratifying a sample of individuals by Celtic/non-Celtic. These data thus magnify differences between people who live in Wales and Scotland and those in England.

The political data employed here are based on the aggregation of parliamentary election results into county data. Within counties, the number of constituencies varies with population.

Measurement

Political disposition. The developmental perspective emphasizes that economic development increases the importance of class-based political cleavages in the polity. Thus, in a fully developed political system, regional variations in the sizes of different classes should explain most, if not all, variations in party support. A primary concern, then, is the nature of regional, political variations which *cannot* be explained by *class* factors.⁴ If they ap-

pear to be random, or at least unsystematic, then the argument that class factors alone are important is supported. If a pattern of excessive support for, or opposition to, a particular political party (that is, *excessive* relative to what one would expect given knowledge of an area's class composition) is detected, then this is evidence of sectionalism. Thus, the central concern is for level of party support *standardized* on class variables. I call this measure of political support *standardized* on class variables "political disposition."

To measure political disposition at the county level, it is necessary to regress county levels of party support on the sizes of different classes and then to examine the residuals from this regression. If an area has more Conservative support than expected according to prediction by class variables, for example, then the political disposition of this area can be described as pro-Conservative. The general form of this estimation technique is:

$$Y = A + B_1x_1 + e,$$

where Y = observed level of party support, x_1 = class variables and e = measure of political disposition. Thus, if an area is mostly working-class but is also a Conservative stronghold, then it probably will have a very large positive residual.

Since the objective is to measure degree of conformity to national patterns of party support, the appropriate dependent variables are the levels of support for the major national parties. In Britain, these are the party in power and the party considered by the electorate to be the loyal opposition. Before World War I, these were the Conservative Party and the Liberal Party. Since the Labour Party, during this period, was an adjunct of the Liberal Party and the Liberal Unionists were allied with the Conservatives, the analysis of the vote for the Liberals and their allies is simply the inverse of the analysis of the vote for the Conservatives and their allies. Thus, only one dependent variable is necessary for the first period.

³ Aggregate ecological analysis is the only mode available for doing quantitative, historical research. Dogan and Rokkan (1969) discuss some of the problems of aggregate analysis.

⁴ Hechter regresses the Conservative vote against a set of interrelated indicators of industrialization, rather than indicators of class composition. However, the developmental perspective emphasizes that with economic development, *class* factors should become more important. Thus, measures of the importance of class in politics should be related to structural differentiation. To regress the vote on indicators of structural differentiation is a totally inap-

propriate test of the developmental perspective. For a review of other analytical and theoretical errors in *Internal Colonialism*, see Ragin (1976).

Since World War I, however, there have been *three* distinct national parties, even though only two have had any real chance of gaining office. Thus, the continued success of the Liberal Party as a third national party and the more recent success of Celtic nationalist parties dictate the use of two dependent variables, Conservative support and Labour support. Furthermore, the Labour and the Conservative Parties are both class-oriented during this period. Labour's primary constituency has been the working class, while the Conservative Party's primary constituency has been the middle classes. Since (1) the vote for one party is *not* the inverse of the vote for the other and (2) both are oriented toward class support, it is necessary to analyze the support of each party separately.

The independent variables of interest here should indicate the nature of the class composition of different areas. The developmental perspective emphasizes that, with economic development, class should dominate politics. Thus, levels of party support should be regressed against measures of the size of different classes in different areas. The goal here is to obtain the best possible predictive model, since the residuals are treated as measures of political disposition. Thus, multiple indicators of class composition are used despite the likelihood of multicollinearity. The following variables are used as measures of class composition:

1. Percentage of the adult male work force employed as *manual workers* in general manufacturing occupations;
2. Percentage of the adult male work force employed as *manual workers* in mines and quarries;
3. Percentage of the adult male work force employed as *manual workers* in heavy industries;
4. Percentage of the adult male work force employed in commercial and professional occupations (nonclerical);
5. Percentage of the adult female work force employed as household domestics.

Note that the first three variables do *not* include *all* adult males employed in those sectors—only those employed in manual

occupations.⁵ Note also that the fourth variable specifically excludes lower white-collar workers. The fifth variable measures class differentials. This measure is particularly suitable because (1) it includes only female *household* domestics and (2) the measure simultaneously indicates the propensity of the middle and upper classes to consume and the need for lower-class women to sell their labor.

Measurement of cultural peripherality. To ascertain the overall importance of cultural (ethnic) factors, Hechter used a set of interrelated indicators of cultural distinctiveness: percentage Nonconformist, percentage Established Church, percentage who speak a Celtic language and a measure of religiosity.⁶ He used multiple indicators in order to exhaust all of the variance in Conservative support that could be explained by cultural factors. However, when he analyzed changes over time in the parameters of a particular model, he used only percentage Nonconformists. Inclusion of all indicators would have introduced severe multicollinearity and rendered the coefficients uninterpretable at each point in time, thus making longitudinal comparisons impossible. I also use a single measure of cultural peripherality, percentage Nonconformists, since I examine a particular model at several points in time.

This measure, percentage Nonconformists, will allow the examination of the extent to which a status factor which indicates a cultural component of ethnicity has influenced Conservative and Labour disposition in British counties over time. The stronger the effect of percentage Nonconformists on the measures of disposition, the stronger the evidence that status-based peripheral sectionalism is a factor in British politics.

Controls for national-regional effects. A pattern of political distinctiveness may be uniform within a peripheral area. This might obtain for historical, particularistic

⁵ The crudeness of census occupational categories, of course, limits precise measurement of numbers of manual and nonmanual workers.

⁶ The measures of religiosity and church affiliation are based on marriage data (see Hechter, 1975:164–206).

reasons not directly addressed by the theories discussed here. For example, an area might consistently and uniformly support a particular party because of the superior organization of the party in that area. When political subdivisions are historically defined, as in the case of Britain, this pattern is particularly favored.

To examine national-regional effects, it is necessary to include in the analysis an indicator for the counties of Scotland and Wales. This can be accomplished by computing two dummy variables, one coded "1" for Scottish counties and "0" for all others, and the other coded "1" for Welsh counties and "0" for all others. The inclusion of these dummy variables allows a more rigorous test of the reactive ethnicity argument.

Cultural peripherality (measured here as percentage Nonconformists) varies within and between national regions. Thus, Wales and Scotland experience relatively higher levels of Nonconformity than England (Hechter, 1975:321-2), but Nonconformity also varies *within* Scotland and Wales. It is necessary, therefore, to control for national-regional effects since Nonconformity is more concentrated in Scotland and Wales. The omission of these controls could permit the effects of uniform national-regional differences to be attributed to Nonconformity.

ANALYSIS

Political Disposition

Table 1 shows the results from regressing Conservative and Labour voting on the five indicators of class composition. The unstandardized regression coefficients reported in this table are used to compute Conservative disposition at eight points in time and Labour disposition at four points in time. These derived, residual measures are used in the analysis below. Note that the causal efficacy of class variables is much greater in the case of Labour support.⁷ This pattern is consistent with the

argument that Conservative and Labour support are fundamentally different and, to gain a complete understanding of political regionalism in Britain, it is necessary to analyze support for both parties separately.

Degree of Sectional Response

The skew of the residuals from the regression of party support on class variables (see Table 2) shows the *degree* of sectional response. A strong skew indicates the possibility of sectionalism because (1) the largest residuals should obtain for *sectional* counties since these counties should conform least to national patterns of party support and (2) the largest residuals should be all positive or all negative since a single pattern of political distinctiveness is expected.⁸ Thus, for example, if Hechter's (1975) argument is correct, Conservative political disposition should manifest a strong negative skew; Labour political disposition, a strong positive skew. This would obtain because Hechter argues that Celtic sectionalism has found expression in an anti-Conservative, pro-Labour posture.

The findings for Conservative disposition are much more consistent than those for Labour disposition. For all but two of the eight elections analyzed, Conservative disposition manifests a strong negative skew. The skew is much stronger after World War I because the Liberal Party remained strong in isolated pockets (mostly at the expense of the Conservative Party). The data for the elections of 1892 and 1900, however, show only very slight skew. These anomalies are probably due to the split between the Liberals and the Liberal Unionists during this period.⁹

⁸ Of course, these measures of skew would be inappropriate if there were two distinct pockets of peripheral sectionalism, with one expressing its sectionalism via strong support for a national party and the other via strong opposition to the same party.

⁹ Votes for the Liberal Unionists have been included as Conservative votes since the Liberal Unionists were allied with the Conservatives. In some areas of the Celtic periphery there was little or no traditional Liberal opposition to the Liberal Unionists. Consequently, these areas appear to be pro-Conservative when they are, in fact, anti-Irish nationalist.

⁷ Since there is a great deal of multicollinearity among these measures of class composition, it is hazardous to interpret the regression coefficients.

Table 1. Regression of Conservative and Labour Votes on Class Composition

Year of Election	% Miners	% Heavy Industries Workers	% Professional and Commercial	% Female Domestics	% Other Industrial Workers	R ²
Conservative Vote						
1885	-.221* (-.340)	-.128 (-.378)	-.113 (-.232)	.495* (1.510)	.276* (.283)	.344
1892	-.216 (-.300)	-.076 (-.237)	.187 (.318)	.069 (.225)	.214 (.191)	.156
1900	-.312* (-.531)	.034 (.216)	.346* (1.107)	.022 (.154)	.200* (.209)	.353
1910	-.233* (-.341)	.363* (.993)	.209* (.479)	.491* (3.555)	.071 (.096)	.466
1924	-.361* (-.474)	.041 (.082)	.018 (.030)	.220 (1.063)	-.136 (-.177)	.269
1931	-.275* (-.463)	.137 (.399)	.164 (.289)	.222 (1.477)	-.040 (-.047)	.239
1951	-.368* (-.720)	.068 (.137)	-.152 (-.153)	.162 (1.124)	-.138 (-.114)	.120
1966	-.332* (-.738)	-.016 (.282)	.020 (.019)	.181 (1.175)	.035 (.028)	.166
Labour Vote						
1924	.471* (.707)	.212* (.494)	.101 (.191)	-.075 (-.416)	.176 (.262)	.386
1931	.587* (.898)	.282* (.748)	.234 (.372)	-.080 (-.485)	.172* (.185)	.558
1951	.469* (.914)	.288* (.582)	.238* (.238)	-.193 (-1.337)	.109 (.089)	.540
1966	.398* (1.049)	.450* (.934)	.167 (.187)	-.121 (-.937)	-.103 (-.096)	.482

Notes: Data are on countries. Unstandardized coefficients in parentheses.

* Denotes significance at .05.

Overall, these data give moderate support to the argument that some sort of sectionalism (anti-Conservatism) has persisted in British politics.

Table 2. Skew of Residuals from the Regression of Conservative and Labour Support on Class Variables

Year of Election	Conservative Residual	Labour Residual
1885	-.858	
1892	-.083	
1900	-.096	
1910	-.516	
1924	-1.017	.387
1931	-.896	.104
1951	-1.365	-.993
1966	-.916	-.039

For Labour disposition, the greatest skew is negative, thus contradicting the reactive ethnicity argument that the Labour Party has served as an outlet for sectionalism. Little, if any, skew is associated with the residuals from the 1931 and 1966 regressions. The one clearly positive skew is for 1924, but this skew is very small in contrast to the large negative Conservative skew for that same election. Overall, there appears to be little support for the argument that the Labour Party has served as a vehicle for sectionalism.

The Social Bases of Sectionalism

The specific nature of sectionalism can be ascertained by regressing Conservative

Table 3. Regression of Conservative and Labour Political Disposition on Nonconformity and Regional Dummy Variables

Year of Election	Nonconformity	Scottish Dummy	Welsh Dummy	R ²
Conservative Political Disposition				
1885	-.609* (-.367)	.045 (.009)	.125 (.033)	.285
1892	-.351* (-.223)	.002 (.005)	-.339* (-.107)	.306
1900	-.446* (-.445)	-.198 (-.069)	-.281* (-.141)	.483
1910	-.628* (-.570)	.199 (.059)	-.176 (-.069)	.476
1924	-.441* (-.396)	.059 (.015)	-.214 (-.087)	.306
1931	-.548* (-.695)	-.188 (-.061)	-.072 (-.033)	.340
1951	-.485* (-.422)	.165* (.039)	-.229 (-.075)	.563
1966	-.782* (-.692)	-.363* (-.078)	.052 (.015)	.487
Labour Political Disposition				
1924	.049 (.045)	.218 (.058)	.135 (.056)	.072
1931	-.087 (-.073)	.066 (.014)	.082 (.025)	.007
1951	-.321 (-.205)	-.375* (-.064)	.354* (.086)	.207
1966	-.328 (-.264)	-.181 (-.036)	.376* (.100)	.081

Note: Unstandardized regression coefficients in parentheses.

* Denotes significance at .05.

and Labour disposition on cultural peripherality (percentage Nonconformists) and the two regional dummy variables (see Table 3). Conservative disposition is analyzed at eight points in time; Labour disposition, at four points.

The findings here support those in Table 2. Analysis of Conservative disposition from 1885 to 1910 shows the persistent association of Nonconformity with anti-Conservatism. The effects of the national regional dummy variables are slight or nonsignificant or both.¹⁰ From 1924 to

1966, percentage Nonconformists again explains much of the variance in Conservative disposition. The unstandardized coefficients show that after World War I the effect of Nonconformity is at least as strong as before the War. Also, the effects of the national-regional dummy variables are again weak or nonsignificant.¹¹

Analysis of Labour disposition produces an entirely different picture. For none of the elections analyzed does percentage Nonconformists have a statistically significant effect. The dummy variables show occasional effects, but these

¹⁰ Wales experienced uniform anti-Conservatism in two of the four elections during this period. This pattern is probably due to the salience of issues associated with the Welsh educational system and the disestablishment of the Church of Wales.

¹¹ The effects of the dummy variable for Scottish counties for 1951 and 1966 reflect the Conservative revival that affected Scotland in the 1950s and its subsequent demise.

effects are neither strong nor consistent. In 1951, for example, Scotland appears to be relatively anti-Labour, while Wales is relatively pro-Labour.

Overall, these data show that while there is evidence of anti-Conservatism in culturally peripheral areas, the Labour Party has not served as an outlet for this sectional sentiment. Indeed, working-class support for the Labour Party appears to be very much the same in all areas of Britain.

DISCUSSION

These findings do not support the theory of reactive ethnic cleavages. This theory is dependent on the argument that an ethnic cleavage will persist if there is a cultural division of labor, and this cleavage will inhibit the development of class-based cleavages. My analysis demonstrates that there are no cultural peripheral effects in Labour support; this suggests that working-class politics are very much the same throughout Britain. To the degree that there is an "ethnic" response, it must occur independently of working-class politics and Labour Party support.¹² A political phenomenon that affects only one of two class-based parties can hardly be described as ethnic in the usual class-denying sense of the term. If peripheral sectionalism in Britain were an ethnic response, then cultural peripheralism would have had a positive effect on Labour disposition. Hechter (1975:292) treats Labour voting as ethnic; the analysis here demonstrates that, in fact, it is not.

With respect to the developmental perspective, the findings here show that the rise of class-based political action does not imply a concomitant decline in political regionalism. Lipset and Rokkan (1967:51) argue that working-class political mobilization in Western democracies during the late nineteenth and early twen-

tieth centuries led to concerted middle-class countermobilization through nationwide mass organizations. This countermobilization has been less than nationwide in Britain, as the Conservative Party has failed to attract its potential supports in the Celtic periphery. This is true despite the relatively uniform class bases of Labour support across regions. Apparently, peripheral sectionalism continues to be a possibility after the development of class politics, but the strength of the peripheral response is limited by class factors.

The analysis of Conservative disposition consistently shows the effects of cultural peripherality, while the analysis of Labour disposition consistently shows the absence of such effects. The non-Conservative proportion of the total vote also must show the effects of status factors since the non-Conservative proportion of the vote is perfectly, negatively correlated with the Conservative proportion. The Labour proportion of the total vote, however, shows no such effects. Therefore, peripheral sectionalism is associated primarily with support for the Liberal Party and the Celtic nationalist parties (i.e., the non-Labour, non-Conservative proportion of the vote).

Alford examined only Labour Party support; he found no significant pattern of political regionalism. He did find higher levels of class voting in Scotland and Wales, but he concluded that the higher levels of class voting in these areas reinforced his conclusion that class alone is important in Britain.¹³ Butler and Stokes, on the other hand, limited their analysis to Conservative and Labour Party supporters, systematically excluding the supporters of the Liberal Party and the Celtic nationalist parties. This procedure obscures the association between cultural peripherality and support for the third parties. Finally, Hechter analyzed only Conservative Party support. Hechter's partial findings have been duplicated here; how-

¹² This is not to imply that political mobilization based on status is necessarily associated with, or generated by, the middle and upper classes. Certain structural conditions such as a split labor market (Bonacich, 1976:34-51) may encourage status-based political mobilization within the working class.

¹³ The fact that there is a higher level of class voting in Scotland and Wales supports the argument that I have presented here—that class cleavages in peripheral areas encourage the local dominant strata to emphasize local culture.

ever, the analysis reported in this paper does not support his argument that the Labour Party has served as an outlet for Celtic peripheral sectionalism.

Peripheral areas in Britain exhibit sectionalism with respect to Conservative Party support, but this does not mean that class factors are irrelevant in these areas. In the Celtic areas of Britain, there is a concomitance of class factors in the vote for Labour and status-based opposition to the Conservative Party. The relative weakness of the Conservative Party, therefore, represents not a failure of class-based political action, but a failure of the Conservative Party among its "natural" constituency.

These findings support the argument that (1) status-based peripheral opposition originates among the local dominant strata of a peripheral area and (2) such opposition is arrested, or at least limited by class cleavages. Thus, emphasis on local culture in peripheral areas may be based in both class and status factors; it cannot be explained simply by one or the other.

The fact that core-periphery conflict originates in and is limited by class cleavages suggests that the primary theoretical question is not whether peripheral opposition is a product of economic gaps between regions. Of greater concern is the relationship between status-group affinity and class affinity in peripheral areas. Some class cleavages in peripheral areas have been transformed into unified opposition to a core area. The evidence I have presented here, however, suggests that the class cleavages that may accompany industrial development (as in Scotland and Wales) hinder the extension of status-group affinity. Thus, the specialized, industrial development of these areas may have stymied the formation of Scottish and Welsh "nations."

Though Hechter misspecified the nature of Labour support in Scotland and Wales, his contrast between Ireland, on the one hand; and Scotland and Wales, on the other, is consistent with this view:

Irish secession is best explained by the *particular mode of dependent development* which emerged in Ireland during the period 1846-1921. This involved the evolution of a relatively capital intensive agrarian regional

economy which did not lead to the substantial inter-regional [working class] organizational affiliations as occurred following the highly restricted industrial development of Wales and Scotland. (Hechter, 1975:292, emphasis added)

Indeed, it is the particular mode of dependent industrial development in Scotland and Wales which best explains the type of (limited) peripheral opposition illustrated in the analysis above.

THE EFFECT OF POLITICAL DEMOCRACY AND SOCIAL DEMOCRACY ON EQUALITY IN INDUSTRIAL SOCIETIES: A CROSS-NATIONAL COMPARISON*

CHRISTOPHER HEWITT

University of Maryland, Baltimore County

American Sociological Review 1977, Vol. 42 (June):450-464

This paper considers the effect of political democracy on the stratification systems of non-communist industrial societies. In contrast to previous research, this study assumes that the effect of democracy will be incremental and, therefore, that the historical experience of democracy must be considered rather than the current political situation. Two hypotheses are suggested: that democracy itself will lead to equality and that only the election of socialist legislatures will lead to equality. The historical experience of democracy and that of socialist legislatures is related to five measures of inequality. It is concluded, after taking into account the level of economic development and the growth rate, that although democracy itself has little effect, the experience of democratic socialist parties is significantly related to variations in inequality. The stronger the democratic socialist parties, the more egalitarian is the contemporary class system.

One important controversy in political sociology and stratification theory concerns the effect of political democracy upon social equality. Some writers argue that political democracy has resulted in a significant modification of the class system in an egalitarian direction. Others take the view that there is no consistent association between political democracy and economic equality, or that the association is spurious once such factors as the level of economic development are taken into account. This paper considers the effect that political democracy has had upon

the stratification systems of non-communist industrial societies.¹

*The author wishes to thank his colleagues Jere Cohen, Ben Kleinberg, Byron Matthews, William Rothstein and Thomas Wan for their comments on an earlier draft of this paper, and Kathleen Peroff of the University of Maryland, College Park, for considerable help with the statistical analysis.

¹ Since the effect of political factors may be very different in developed and underdeveloped nations, the analysis has been limited to those countries which can be considered "modern industrial." A nation was defined as modern industrial if it was above the mean in both per capita income and per capita energy consumption in 1965 according to the tables in Taylor and Hudson (1972: Tables 5-5, 5-7). Thirty-four countries fitted both these criteria, and four countries fitted one. The thirty-four countries were reduced to twenty-five by the exclusion of seven communist nations and two countries (Kuwait and Iceland) for which no equality measures could be found. The measures of equality used in the study refer in almost all cases to the 1960-1965 period. A further reason for focusing on developed countries is given by Wilensky (1975:xiii) who argues that it is "necessary because of well-known limitations of data. Rich countries are at once rich in goods and services and rich in data; statistical records of less affluent countries are, in contrast, quite weak." The position adopted in this paper is similar to Wilen-

THEORETICAL BACKGROUND

The view that political democracy leads to greater economic equality is an old one and was held by both radicals and conservatives in the late eighteenth- and early nineteenth-century period. During the debate over the 1832 Reform Bill in England (which increased the franchise to 3.1% of the total population), John Stuart Mill foresaw the prospect of a revolution that would "exterminate every person in Great Britain and Ireland who has £500 a year." John Wilson Croker, the leading Tory publicist of the day, expected the result would be "no King, no Lords, no inequalities in the social system; all will be leveled to the plane of petty shopkeepers and small farmers" (Jaher, 1973:206). More recently, Lenski (1966:312-25) has revived the argument, although in a slightly ambiguous fashion. Initially, Lenski makes a purely deductive argument about the redistributive significance of democracy based upon two assumptions. The first assumption is that "those who control the government are able to determine the rules governing the competition for rewards in society, and by virtue of this power are able to influence profoundly the outcome of this competition." The second assumption is that political democracy has shifted significantly the distribution of political power from the rich to the poor. However, in his subsequent discussion of "the outcomes of the struggles for power in the more advanced industrial democracies," Lenski formulates his argument in terms of the relative significance of socialist parties in different countries. This suggests that one may put forward two alternative hypotheses as to the effect of political democracy upon equality: the "social democratic" and the "simple democratic" hypotheses. No assumption is made that these hypotheses are related nor that democracy will lead to socialism.²

sky's, that a small number of accurate and appropriately chosen observations are of more value than a large number of poor ones.

² For the sample of countries analyzed in this study, the correlation between democratic experience and socialist strength is only .30, which is not statistically significant at the .05 level.

Social Democratic Hypothesis

Political democracy is not a sufficient condition for the achievement of a more equal society. The crucial matter is what the mass electorate *does* with the franchise and other democratic procedures. Only if the lower classes use their votes to elect socialist governments will democracy result in more equality, since non-socialist governments will not be concerned with redistribution and social equality (Parkin, 1971:105).

Simple Democratic Hypothesis

Regardless of the strength of socialist parties, the existence of a mass electorate in which a majority of the voters are drawn from the working class will have egalitarian consequences. This will happen because generally there will be a class polarization of voting so that one party will be "the working-class party" in terms of support and will function in the same fashion as an explicitly socialist party. Lipset (1960) provides a much-quoted summary of this view in which elections are seen as "the expression of the democratic class struggle." Ausubel (1960) claims that the New Zealand Labor Party is no more radical than the Democratic Party in the United States. Also, the parties which manifestly represent middle-class interests or non-class interests will have to attract substantial working-class support and will carry out some policies to benefit them. The social policies of conservatives such as Bismarck and Disraeli, for example, are conventionally interpreted as responses to the increase in the franchise and as attempts to reduce the appeal of the growing socialist movement.

The empirical evidence presented by Lenski in support of either hypothesis is inconclusive. He shows that "industrial" societies have a much more equal distribution of income than do "agrarian" societies and also a much greater diffusion of political power. Yet, since the difference in income distribution between the two types of society could be a result of economic differences, the redistributive effects of democracy are unproven. His view that socialist countries are more

equal than non-socialist countries is supported only by impressionistic evidence.³

Those who argue that political democracy has not resulted in a more equal stratification system fall into two schools, the Functionalists and the Marxists. The Functionalists argue that the form of government, whether democratic or non-democratic, socialist or non-socialist, does not affect the stratification system since the "needs" of modern industrial economies will require similar differentials in earnings between occupational groups, similar mobility rates and similar government policies, etc. Any changes in the distributive system are explained as a result of the "logic of industrialism." Industrial and technological changes lead to a convergent pattern of development in the stratification systems of all advanced industrial societies, regardless of politics.⁴

Like the Functionalists, though for different reasons, the Marxists assume that politics, as practiced in non-communist societies at least, has very little impact. Through its economic power, the capitalist class is able to dominate or control the state and, in turn, use their power over the state to maintain their economic position. In consequence, formal democracy is largely a sham. Social democratic parties have used an egalitarian rhetoric, but have rarely translated this into effective policies (Miliband, 1969:22; Parkin, 1971:105).

³ Lenski (1966:308-18) argues that the Swedish Social Democratic Party's policies "have been directed consistently toward the goal of advancing the interests of the working class, and have resulted in the creation of a welfare state in which social inequalities of nearly every kind have been substantially reduced In the United States, the situation is quite different" (Lenski, 1966:320). The only comparison of the actual degree of inequality in Sweden and the United States, however, is to be found in his later book, *Human Societies* (Lenski, 1974:370), where a table showing the distribution of wealth in the two countries is described as showing the "modest success [of the working class] in its efforts to effect a redistribution of income and reduce the economic and political power of the propertied elite."

⁴ The most cited statement of this position can be found in Kerr (1964). Inkeles and Rossi (1956) have shown that the ranking of occupations is very similar in industrial societies, and Mishra (1973) shows that there is a convergence in their social welfare policies.

Existing research on cross-national variations in economic equality generally has concluded that differences in political systems are not associated with the degree of inequality, or that such variations can be adequately explained by economic factors. Cutright (1967a) found that variations in "intersectoral income inequality" among high GNP nations were not related to differences in their "Political Representativeness Index" scores and could be explained instead by four economic factors.⁵ In a second paper, Cutright (1967b) suggested that the variance in the percent of GNP allocated to Social Security expenditures is mainly attributable to variations in the "experience and power of the Social Security bureaucracy." After this is correlated with expenditures, the percent of the voting-age population voting in national elections during the 1950s (his measure of equalitarian pressure in the political system) has no additional effect. Parkin (1971) measures "the impact of socialist governments on the reward structure of capitalist society" by comparing the stratification systems of Western countries which have had significant periods of social democratic government with those which have not. He makes a simple dichotomy between the Scandinavian countries and Britain, on one hand, and the other countries of Western Europe, on the other, and compares the two groups on various measures. The findings are that social mobility and educational opportunity are greater in the social democratic countries, but that there are no differences in either the provision of social services or in income differentials between oc-

⁵ More precisely, since "there is no meaningful difference among these nations in their Political Representativeness Index scores," Cutright omits this variable from his analysis. It should be noted that Cutright does not consider his four variables (proportion of farms rented, military participation ratio, capital formation and proportion of foreign trade) to be purely economic but, rather, indirect indicators of power relations between nations or between groups in a given society. It should be noted also that six of the nations considered in the present study are classified as having middle levels of GNP per capita by Cutright, and that for middle GNP per capita nations, the index is significantly related to the inequality measure.

cupational groups between the two groups of countries.

Wilensky concludes, on the basis of a cross-sectional analysis of sixty-four countries, that economic growth and its demographic and bureaucratic outcomes are the root cause of the general emergence of the welfare state. In any systematic comparison, "alternative explanations collapse under the weight of such heavy, brittle categories as 'socialist' versus 'capitalist' economies, 'collectivistic' versus 'individualistic' ideologies, or even 'democratic' versus 'totalitarian' political systems . . . these categories are almost useless in explaining the origins and general development of the welfare state" (Wilensky, 1975:xiii, 47). However, for the most developed nations, there are "sharp differences in the level of welfare" spending, and Wilensky (1975:50ff.) suggests that socio-political factors may affect such variations.

The most recent research reported is by Jackman (1974; 1975), who concluded that neither political democracy nor socialism have any significant effect on three measures of social equality once the level of economic development is taken into account.

Although some of these findings can be interpreted in ways that allow more significance to political factors, the consensus of these studies is that neither democracy itself nor the use of democracy to elect socialist governments has any important independent effect in reducing inequality. However, such a conclusion requires that one accept the various measures of social equality, democracy and socialism that have been used in these studies. It will be argued below that the measures previously used are not valid indicators of any of these concepts and alternative measures will be proposed.

THE DEPENDENT VARIABLES

Measures of social equality fall into three groups: measures of government redistribution, measures of income inequality and measures of opportunity.

Government Redistribution

Cutright and Parkin both use the proportion of GNP devoted to social service expenditures as a measure of government redistributive efforts. However, social service expenditures are not a good measure of the redistributive effect of government activities. This is because although such expenditures disproportionately benefit lower socioeconomic groups and individuals, the money spent on social services is, in part, raised from taxes upon these same groups and individuals. To estimate the net redistribution carried out by the government, one must simultaneously consider the effect of both the taxation system and social service expenditures. At present, the data for a sophisticated analysis do not exist, but a simplified measure can be calculated which will allow cross-national comparisons. On the assumption that direct taxes on income are generally "progressive" while indirect taxes (sales taxes, etc.) are generally "regressive," it can be argued that *only* that proportion of social service expenditures which is raised from direct taxes should be considered as a measure of net redistribution.⁶

Income Inequality

Cutright (1967a) and Jackman (1974; 1975) both use a rather unsatisfactory measure of income inequality termed "intersectoral income inequality," which measures the disproportion of income and population between industrial sectors. This is viewed by both writers as a substitute measure for *individual* income distribution data which are unavailable for many of the low- and middle-income

⁶ For an analysis of redistribution in Britain under the postwar Labour Government which illustrates well the intellectual issues in the controversy, see Peacock (1954) and Cartter (1955). The figures in the column headed "Redistributive Effect" exaggerate the net effect of government budgets since personal income taxes are calculated as a percentage of personal income rather than GNP, as is the case for indirect taxes. This makes the ratio used higher than the real statistic of direct to total taxes for all countries.

Table 1. Redistributive Effect of Government Budget (1962-1964)*

	Income Tax ^b	Indirect Taxes ^c	Social Service Expenditures ^d	Redistributive Effect ^e
Sweden	19.6	12.6	15.6	9.5
Austria	13.3	15.6	20.2	9.3
Netherlands	13.1	10.1	15.6	8.8
Germany	11.4	14.3	18.6	8.3
Norway	18.8	14.4	12.2	6.9
New Zealand	16.1	10.5	11.3	6.8

* Table includes all non-communist countries listed in Wilensky (1975: Table 2); except Israel and Italy, for which no figures on personal income were available.

^b Column 1 from U.N. (1967: Table 6.3), except non-European countries. Personal income tax expressed as a percentage of personal income (1962-1964 average).

^c Column 2 from U.N. (1967: ch. 6, p. 9), except non-European countries. Indirect taxes expressed as a percentage of GNP (1962-1964 average). Figures for U.S., Canada, New Zealand, Australia and Japan in columns 1 and 2 calculated by author for same years from U.N. Yearbook of National Accounts Statistics (1966).

^d Column 3 from Wilensky (1975: Table 2). Social Security spending expressed as a percentage of GNP in 1964.

^e Column 4 = $\frac{\text{Column 1}}{\text{Column 1} + \text{Column 2}} \times \text{Column 3}$.

countries they analyzed.⁷ This assumption of a congruence between the two measures is not accepted by Taylor and Hudson (1972)⁸ nor supported by the re-

⁷ See Cutright (1967a:564). "Kuznets . . . using limited data and economic theory, argues persuasively that nations ordered by the degree of inequality on intersectoral income will have much the same order as nations ordered by individual earner measures of inequality."

His final comment that "this is powerful validation of Kuznets' theory, and strengthens our use of intersectoral inequality scores in place of (unavailable) inequality data based on individuals" clearly implies that intersectoral inequality is a proxy measure for individual income inequality. Jackman (1975:20) says that "unfortunately, income data collected at the family or consuming-unit level are not available for enough countries for us to be able to test this argument cross-nationally. Such data (if available) would be preferable to the intersectoral data, which are used as an approximation to the disaggregated data."

⁸ Taylor and Hudson (1972:213) say of intersectoral income measures that "the kind of index does make a difference In any event, the series . . . must not be used as if it measured inequality of income among households; it does not."

search of Husbands and Money (1970). Certainly, if a choice were possible, it is hard to see why intersectoral would be chosen over individual income data, since almost all the theoretical literature on income inequality obviously is referring to the latter kind of distribution. A statement that income was becoming more equally distributed in a particular society rarely would be taken to imply that "electricity, gas, water, and sanitary service" workers' incomes were becoming more similar to those of workers in "mining and quarrying" (two of the eight industrial sectors). Instead, it would be assumed that the statement referred to lower-income individuals and households receiving a higher proportion of the national income.

The distributions of intersectoral inequality relate quite well to economic development—the greater the development, the less the inequality among sectors—but for nine countries, Kuznets found no significant relationship between Gini numbers based upon household data and Gini numbers based upon sectoral data" (emphasis in the original).

It could be argued that the accuracy and comparability of household income distribution data leave much to be desired. While this is so, such an objection could be raised against almost all cross-national series. Furthermore, in the present study, individual or household income data are calculated only for industrial societies with well-developed government bureaucracies, while over half the countries in the studies of Cutright or Jackman are non-industrial with small and inefficient statistical reporting systems and large subsistence sectors. Any claim that their sectoral income measures were more accurate than the household income measures used in this study would be hard to support.

Parkin (1971) measures income inequality by the ratios of the average earnings of different occupational groups (e.g., unskilled labor to managerial). Two obvious problems in using these data are that occupational classifications vary between countries and that income differentials *within* occupational categories are ignored (e.g., between high paid and low paid unskilled laborers).

Three measures of income inequality are used in the present study, all of which measure the distribution of income between individuals or households. The first measure is the spread of earned income between labor force participants and is calculated by taking the difference between the earnings of high- and low-paid percentiles of workers and expressing this as a percentage of the median income. The resulting figure yields a measure of the range or spread of earnings. The statistics used are those calculated by Lydall (1968) and Pryor (1971).⁹

The labor force measure ignores one important source of inequality in capitalist society, unearned income accruing to the owners of property. A large proportion of this, however, goes to the highest income

groups and the second and third measures, which are the shares of national income going to the highest twentieth and quintile of income recipients, include the effect of this as well as the effect of high salaries. The most recent and comprehensive set of statistics on the size distribution of income are those of Paukert (1973), which, with minor modifications suggested by Atkinson (1975), are used in the present study.¹⁰

Equal Opportunity

The mobility rates between classes provide one measure of the "openness" of the stratification system. However, mobility studies such as the one by Miller (1960) which Parkin cites are based on competed mobility by mature adults of varying ages and do not provide a measure of *current* mobility chances. Given that this is now largely mediated by the opportunities for education available, it seems reasonable to use access to higher education as a measure of opportunity.

Access to higher education by the lower classes is a result of two factors in combination, the *amount* of higher education and the *proportion* of university students from the lower classes. The index of opportunity is constructed, therefore, by multiplying the proportion of students receiving higher education (as a percentage of the 20–24-year-olds) by the proportion of non-middle-class students in higher education.¹¹

¹⁰ Paukert's figures are derived in large part from a compilation by Adelman and Taft Morris (1973) and include data on the distribution of income by size for 56 countries. Atkinson (1975) has suggested some minor changes in Paukert's figures. The literature on the distribution of income by size is extensive and, in addition to the classic studies by Kuznets (1963) and Kravis (1960), Pen (1971) and Champernowne (1973) should be consulted. Recent analyses by some economists have suggested that statistics on household income exaggerate the degree of inequality in developed societies. Prosperity enables old and young to live in separate households and paradoxically increases the proportion of poor households. In less developed societies with more traditional family systems, young adults and the old live as dependents in extended families whose aggregate family income is higher (Paglin, 1975). This suggests again the advantage of comparing societies at the same general level of development.

¹¹ The statistics are taken from OECD (1971)

⁹ The statistics were first calculated by Lydall and refer to "male adults, in all occupations, in all industries except farming, in all areas, working full-time and for the full period. The income measured should be money wages and salaries only, and before tax" (Lydall, 1968:60). Pryor (1971) further developed the measure and calculated the statistic for some additional countries.

INDEPENDENT VARIABLES

The effect of political democracy or of socialist parties on equality clearly has not been revolutionary. In fact, it has been precisely the belief in the possibilities of gradual incremental reform within a democratic context that has always distinguished social democratic parties from revolutionary Marxist parties, whether Communist or Trotskyite. The implication of this is that it is not the current situation as regards democracy or socialism that must be considered but, rather, the historical experience over the last few decades. Unfortunately, both of Cutright's papers and Jackman's recent paper and book define democracy and socialism in terms of the contemporary situation in the countries they examine while ignoring the historical dimension almost entirely. For example, Jackman's (1975:127) "measure of Socialist Party strength is the proportion of seats in the national legislature held by parties of the non-Communist left . . . taking the average of the number of such seats in both the last legislature created before 1960 as well as the first created after that date." Thus, the country, which, according to Jackman, displays the greatest socialist party strength, is Venezuela, which is scored as 91.5% socialist. However, to expect Betancourt's *Accion Democratica* government to have achieved much in the way of egalitarian reforms is somewhat unfair, since it had only been in power since 1958. Prior to that (except for one election and less

compilations which break down the social background of students into five categories, A, B, C, D and E. The A and B categories are higher and lower white-collar parents, respectively, while the C and D categories include "independent agriculturalists" and "self-employed workers." The E category is referred to as "lower-" class occupations. It was decided to define non-middle class as including all the non-A or B background students, rather than as just the E background students. This is based on two considerations. In most countries (particularly in Western Europe), the C and D categories are more reasonably considered as belonging to the lower strata (in terms of income and education, for example) than they are to the white-collar occupations. Also, since not all the countries report C and D social origins, it seems likely that in such cases they are grouped under the lower class which makes variations in the E category somewhat suspect.

than two years of democratic politics in 1946-1948), Venezuela had been ruled by a variety of military dictators. The figures are similarly misleading for almost all the third world countries included in Jackman's sample, since, if they did have socialist parties in 1960, these were comparatively recent innovations after decades of colonial or dictatorial rule. The same reasons can be given for dismissing Jackman's measure of democratic performance and, to a lesser degree, objecting to Cutright's measures.¹²

Democratic Experience

There are many possible definitions of political democracy. At a minimum, however, three characteristics must be possessed by a state before popular usage would justify the term being used, and which might have egalitarian consequences.

(1) The executive must be elected, or must be responsible to an elected assembly.

Although in some countries, the transition to responsible government can be marked precisely when revolutions overthrew absolutist monarchies or constitutions were granted, in many cases the transition is a gradual process. Hence, the most that can be said about the selection of a particular date is that its arbitrariness is inevitable and, where possible, follows the conventional opinion of most historians.

(2) There should be universal manhood suffrage.

Universal suffrage is considered to exist when virtually all adult males have the vote. Disfranchisement on account of age or sex is ignored, since this study focuses

¹² Cutright's (1967a) Political Representativeness Index refers to the 1945-1954 period and his voting measure refers to the proportion of adults voting in national elections during the 1950s (1967b). Jackman's (1975:64-5) measure of democratic performance appears to relate to a single election or point in time. Largely in consequence of this, there is only a very slight variation in democratic performance scores between the industrialized countries (two score in the forties, one in the seventies, nineteen in the eighties and Trinidad, with a score of ninety, is, surprisingly, the most "democratic" country in his sample).

on the consequences of democracy for the class system.

(3) Elections should be "fair," as indicated by the presence of a secret ballot.

Only one indicator of electoral "fairness" is used, the adoption of the secret ballot, since this prevents or greatly reduces intimidation, bribery, and most other abuses, and is also probably symbolic of a general reform orientation (Rokkan, 1961). Secret ballots were used in the United States and France before the data cited, but were so ineffective that the dates given refer to the introduction of the "Australian ballot."

Democratic scores have been calculated on the assumption that to be democratic a state must *simultaneously* fulfill all three requirements. The scores represent the number of years since the states became fully democratic, less any subsequent period of dictatorship or foreign military occupation.

Currently, almost all the non-communist industrial societies which will

be considered in this paper are democracies as evaluated by the criteria above. However, there are important differences between these societies in terms of how long they have been democratic as can be seen from Table 2.

Experience of Social Democracy

The term "social democratic" is used here to describe those movements and parties which avowedly embody socialist ideals or claim to represent the working class or labor interest, and also are committed to the norms of representative democracy. Specifically, social democracy is defined as including those parties which are affiliated to the Socialist International, thereby guaranteeing a certain ideological and programmatic homogeneity to the grouping.¹³ Alternative definitions are, of

¹³ The People's National Movement of Trinidad had contacts with the Socialist International until 1962 and fought the 1958 federal West Indies elec-

course, possible. Jackman takes the term "Socialist" to be synonymous with "non-Communist Left" as used in the *World Handbook of Political and Social Indicators*. The original source of the data is an annual U.S. State Department publication primarily concerned, according to its title, with the *World Strength of Communist Party Organizations*. Incidental to this purpose, the State Department compilers provide a rough classification of other political groupings. There is no description of the rationale behind this classification into "non-Communist Left," "Center" and "Conservative" parties; for example, whether it measures domestic liberalism or foreign policy alignments or both.¹⁴ Nor does the State Department usage appear to be consistent between countries nor even within the same country at different times.¹⁵ The concept of a "Left-Center-Right" spectrum, though of considerable utility in most Western politics, should be used with extreme caution outside this context as almost every student of third world politics stresses.¹⁶ The U.S. State De-

partment category of "non-Communist Left" is a wide and heterogeneous grouping of parties unlikely to play a uniform role. It includes Catholic parties, middle-class radical parties and even groups such as the Peronists of Argentina.¹⁷

The measure of socialist party strength used here is the annual average proportion of seats held by socialist parties in the national legislature, over the first twenty postwar years.¹⁸ This measure takes account of the fact that socialist parties may have an impact even when in opposition as the non-socialist parties try to forestall the appeal of the socialists by adopting some of their policies.

FINDINGS

It has been hypothesized that the experience of either democracy or socialism might have an egalitarian effect upon stratification systems. The most straightforward test of this is to see whether there is any association between the two political history measures and the five measures of equality. Table 4 presents the simple correlations between democracy and socialism and each of the measures of equality. The figures show that at least one political variable is significantly associated with each of the equality measures. The statistically significant associations are as follows. The more democracy or socialism a country has experienced, the lower the share of the national income taken by the highest income categories. The more democratic experience, the narrower the range of earnings between high and low paid work-

tions as a constituent of the Federal Labour Party (Ayeerst, 1960:213). It is, therefore, included as a socialist party, though no longer in contact with the International.

¹⁴ Thus, in Guyana, the People's Progressive Party split into two factions, one led by Burnham and one by Jagan. The polarization was primarily on racial (i.e., Negro versus East Indian) lines, and the two groups had no discernible domestic policy differences. However, Jagan's flirtation with a pro-Soviet/anti-American foreign policy led to his faction being dubbed "Communist" by the U.S. State Department.

¹⁵ An example of this is in the treatment of Trinidad's PNM which, as part of the Federal Labour Party, won four out of ten seats in the 1958 federal elections and twenty out of thirty seats in the 1961 elections. The Democratic Labour Party won the remaining seats in both elections. In 1958, the State Department classified the PNM as "non-Communist left," but as a "center" party in 1961. Therefore, Trinidad's "Socialist" score involves the same party being counted once as Socialist and once as non-Socialist.

¹⁶ Gil (1966:44) says of Chile that it "is the only Latin American country where political forces are clearly and distinctly aligned . . . into three great blocks: Right, Center and Left." The State Department (1968:81) publication itself comments regarding Japan that "political parties are divided into 'ins' and 'outs' and the term 'center' has little meaning" and, in the 1961 edition, classified most Latin American

parties according to whether they were "Ruling" or "Opposition."

¹⁷ In the four third world countries considered here whose parties are classified by the State Department, only four out of twelve "non-Communist left" parties are members of the Socialist International. Furthermore, two parties which were associated with the Socialist International, the Democratic Socialist Party of Japan and the PNM of Trinidad, are classified as "center" parties.

¹⁸ Alternative measures of the strength of socialism such as the proportion of workers unionized, the socialist party vote or the years in which socialist parties were governing had very high intercorrelations and all correlation coefficients were significant at the .05 level.

ers. Strong socialist movements are associated with a greater proportion of the national income being redistributed. All these associations are in the anticipated direction. However, no association is found between democracy and access to higher education by non-middle-class youth and strong socialist movements appear to be *inversely* related to such access. These results clearly contradict Parkins' argument that the socialist countries are not more egalitarian, but are more open societies in which educational opportunities are greater for the lower strata. Table 4 suggests the opposite conclusions; socialist societies are more equal but less educationally open than the less socialist countries. This finding could perhaps be explained by Lipset's argument concerning the inverse relationship between a concern with equality and a concern with achievement (or equality of opportunity). Socialist countries stress

the former, while the more "liberal" countries emphasize the latter (Lipset 1963: 259-61, 321).

Some other critics of the thesis that political factors, such as democracy or socialism, cause societies to become more egalitarian have taken a different and slightly more complex position. Critics, such as Jackman (1975:85, 151), argue that although democracy (or socialism) may be positively associated with equality, this relationship is seen to be spurious once the level of economic development is taken into account. In other words, economic development is responsible for both the growth of democracy (or socialism) and for the decline in inequality, but there is no direct causal relationship between the political variables and inequality. That there is a significant positive relationship between the level of economic development and income equality appears unquestionable. It was noted in the pioneering work of Kuznets (1955; 1963), Oshima (1962), Kravis (1960) and Lydall (1968), and recent analyses on larger samples of countries by Adelman and Taft Morris (1973) and Paukert (1973) have come to the same conclusions. There are some disagreements as to the form that this relationship takes, but they are not relevant for the present analysis.¹⁹ There appears to be a similar positive rela-

¹⁹ Kuznets (1955) thinks that inequality may have increased in the early phases of economic growth, then stabilized, and finally narrowed. On the other hand, Jackman argues for a curvilinear relationship in which economic development has less effect in reducing inequality at the higher levels of development. However, since the present analysis is concerned with only the most developed countries, the relationship can be assumed to be linear.

tionship between economic development and the growth of the welfare state (Cutright, 1967b; Wilensky, 1975). The fiscal system in developed countries places more reliance upon direct rather than indirect taxes (Musgrave, 1969:142-7), which also seems likely to have egalitarian effects. It has also been suggested that a connection between high rates of economic growth and inequality may exist (Olson, 1963) and Jackman's data (1975:43-7) appear to support this argument.

To see whether the political variables are still related to inequality even after taking into account the two economic variables, multiple regression analysis was used. In order that this test of the effect of the economic variables be a thorough one, both economic development and economic growth were operationalized in two ways. Economic development was measured in terms of GNP/capita and also in terms of energy consumption/capita, while economic growth was measured in terms of the average annual rate of change in both of these measures during the 1950-1965 period (Taylor and Hudson, 1972). Table 5 presents the results of the regression analysis.²⁰

In eleven of the forty multiple regression equations, the economic control proved to have a significant impact upon the equality measure. Economic development was a much better control than the economic growth rate, being significantly related to equality in eight cases of the eleven.

The data do not support the argument that the relationship between socialism and equality is a spurious one when economic factors are taken into account. Socialism is consistently and positively related to government redistribution and to a lowering of the share of the top income groups, regardless of the economic control being considered.

The relationship between democracy

²⁰ Space limitations dictate that only the results of the regressions which operationalize economic development or growth in terms of energy consumption are shown. The energy consumption measures have a slightly stronger relationship to the equality measures than do the GNP measures.

and income equality does appear less obvious when economic variables are considered simultaneously. The previous association between democracy and labor force earnings spread disappears whatever economic control is used. Also, controlling for GNP/capita makes any association between democracy and any measure of equality disappear. It is therefore plausible to assume that the apparent relationship between democracy and equality is indeed a spurious one.²¹

To test the hypotheses with a more fully specified model, all the variables (socialist experience, democratic experience, economic development and economic growth rate) are considered together to see what relative effect they have on the equality measures. For the most part, Table 6 reveals the same pattern found in earlier models. Socialist experience is significantly related in the predicted direction to redistribution through government budgets and to the share of national income going to the top income groups. Democratic experience exerts no effect on the equality measures, with the exception of the share of national income going to the top five percent of income recipients.

DISCUSSION

The preceding analysis suggests that while one may reject the "simple democratic hypothesis," the evidence on cross-national variations in equality is clearly compatible with the "social-democratic hypothesis." Strong socialist parties acting within a democratic framework appear to have reduced inequality in industrial societies. If one accepts this conclusion, it has highly important implications. First, it encourages op-

²¹ The independent variables are associated as follows. Pearsonian correlation coefficients significant at the .05 level are starred.

	2	3	4
1. Democracy	.30	.40*	-.67*
2. Socialism		-.05	-.26
3. Economic Development			-.50*
4. Economic Growth			

It is possible that the insignificant relationship between democracy and equality when we control for economic variables may be due to the collinearity between economic variables and democracy.

timism about the possibilities of political action to reduce inequality. Second, the finding that political factors do affect the stratification system has obvious relevance for the two major orientations in stratification theory, Functionalism and Marxism, both of which deny or ignore

such a possibility. Our findings are even more significant because, almost without exception, previous research has come to the opposite conclusions. It has become a virtual convention to acknowledge the deficiencies of the data which must be used in cross-national studies. It is possible,

therefore, that better data might change the relationship that has been reported here between social democracy and equality. However, there is evidence which suggests that if better data allowing more precise measurement could be found, the relationship might appear stronger rather than weaker. For example, the measure of redistribution via government budgets used here involves a simple distinction between direct (progressive) and indirect (regressive) taxes. Some direct taxes are, however, more progressive than others and some indirect taxes may, in fact, be quite progressive. Furthermore, it is, in general, the more social democratic countries that have a high ratio of direct to indirect taxes, and, *within* each category of taxes, adopt procedures that place a greater burden on higher income individuals.²² The small

number of countries which can be examined is obviously a problem. However, the growing interest in public policy and income distribution as well as cooperation between nations in such organizations as the OECD or the EEC is likely to generate measures of equality for those industrial societies which lack such information at present and to lead to a standardization of such measures between countries.

Any conclusions as to the significance of political factors in affecting the class system based on the type of data that must at present be used in cross-national comparisons, should be very tentative. In consequence, this study is not to be seen as definitive but, hopefully it will serve as a stimulus to other researchers to generate new measures of equality and political participation and to examine the relationships between them.²³

²² The U.N. Survey (1967:24) suggested that the progressiveness of income taxes was highest in Sweden, Norway, the UK and Netherlands and lowest in West Germany, Denmark, France and Italy. With regard to indirect taxes, Germany, France, Austria, Belgium, Italy and the Netherlands have a general turnover tax or value-added tax in which the incidence is more or less proportional to household expenditure. In Britain, Denmark and Sweden, indirect taxes are more concentrated on items such as drink, tobacco, automobiles, and petroleum products (U.N. Survey, 1967:8).

²³ For example, longitudinal analysis of individual countries should yield the same results as our cross-national analysis. The Swedish case supports this argument. "A systematic comparison of the pre-tax distribution of income in four European nations and the United States showed that in 1935 Sweden began with 'the most unequal distribution of any we have recorded and wound up in 1954 with one of the least unequal. . . . In 1932, a national crisis brought the Social Democrats and the Farmers' Party to power and cast the die for the accelerated development of the most celebrated welfare state of our time'" (Wilensky, 1975:73).

THE ETHNIC VICE INDUSTRY, 1880-1944*

IVAN LIGHT

University of California, Los Angeles

American Sociological Review 1977, Vol. 42 (June):464-479

Sociologists have explained the association of ethnic minorities and illegal enterprise in terms of structural blockages and opportunities, emphatically denying any ethnic contribution. A comparison of blacks and Chinese in the vice industry, 1880-1940, confirms the guiding role of American society which rewarded ethnics' participation in prostitution but restricted legal earning opportunities. Nonetheless, divergent demographic and cultural characteristics of Chinese and blacks differentially affected the internal organization of each group's vice industry as well as the process of industrial succession. This finding supports a view of illegal enterprise as a synthesis of illegal work that consumers want to buy and what disadvantaged ethnics have to offer. In general, socio-cultural characteristics of provider subgroups define the manner in which they respond to consumer demand for illegal products and services.

ILLEGAL ENTERPRISE

The major revenues of organized crime derive from the sale of illegal products and services. In this respect, organized crime is a business and has long been so acknowledged (Stone, 1926; Ogburn, 1937:10; Sellin, 1963; Haller, 1970:623; Lasswell, 1972:108; Ianni, 1974:15). The familiar term "organized crime" encompasses, however, some predatory crimes (hijacking, burglary, labor and business racketeering, etc.) as well as the demand-oriented sale of illegal products and services (Landesco, 1968:149-67; Seidman, 1938; MacMichael, 1970; Cressey, 1972:5, 8, 11, 26-7; Schelling, 1971). To designate the demand-oriented, illegal business only, Vold (1958:396-7) and Albin (1971:47) recommended the term "syndicated crime." However, they apply this term only to illegal enterprises

which encompass two or more retail outlets. "Syndicated crime" excludes small, independent, illegal businesses such as "single-action" numbers banking. Smith (1975:335) defines "illicit enterprise" as the "extension of legitimate market activities into areas normally proscribed . . . for the pursuit of profit and in response to latent illicit demand." This definition satisfactorily encompasses every form of demand-oriented, illegal business while excluding predatory crime. Unfortunately, the term "illicit" has the value connotation of impropriety. Therefore, Haller's (1970:623) term "illegal enterprise" is the most neutral designation for every type and size of business enterprise which supplies illegal products or services to willing consumers.

A large and often polemical literature has developed around the putative connection of ethnic groups and syndicated crime. This debate long revolved around the issue of whether syndicated crime is a foreign import or a product of American social conditions. Of these polarities, the

*A grant from the Los Angeles Division of the Academic Senate, University of California, assisted the preparation of documents for this research.

import theory was the older. The police, Senate investigators, and vocal sectors of the American public have recurrently interpreted syndicated crime here as trans-plantation of secret organizations, cultural forms and even biological strains native to benighted parts of the world (California Department of Justice, 1973; Moore, 1974:viii, 40, 237). The import theory was a convenient vehicle for xenophobia and chauvinism, so racist, nativist and patriotic groups climbed aboard.

In reaction to the import theory, Landesco (1968; cf. Haller, 1968:xiii) and subsequent sociologists have minimized any ethnic contribution to syndicated crime in this country, claiming instead that American social conditions made criminals of oppressed slum dwellers. King (1969:183) calls this issue "the key question in the continuing debate over the nature of organized crime." The sharpest, most influential attack was that of Bell (1960:127, 138) who tagged the rackets "an American Way of Life" and lampooned the "myth of the Mafia." Tyler (1962:xiii) insisted that syndicated crime here is "a product and reflection of our national culture" rather than an alien importation. More recently, Albin (1971:154) concluded that "syndicated crime in the United States has developed from within the American social structure." Albin contrasts this conclusion with "the widely held misconception" that syndicated crime is "a product of foreign evildoers" seeking to "rob the American public of its moral virginity."

Two persuasive types of evidence have supported the long-prevailing sociological view that illegal enterprise is domestic rather than alien in origin. The first depends upon the observation that illegal enterprise satisfies the demand of the American public for illegal products and services (Albin, 1971:47) including gambling, usurious loans, pornography, prostitution, narcotics and, during the Prohibition era (1919-1933), liquor. Americans buy these illegal products and services because they want them, even at the high prices typically charged. Indeed, as Sutherland and Cressey (1970:272) observe, if crime syndicates abruptly disappeared, they would be "sorely missed"

because they perform services "for which there is a great public demand." Since the syndicates cannot exist apart from the public demand they satisfy, the American public's demand for illegal services and products is, in this view, the ultimate cause of the syndicate. Demand begets supply.

The theory of ethnic succession provided a second prop for the assertion that illegal enterprise was domestic in origin rather than imported. This usage paralleled the case for ethnic succession in juvenile delinquency which Shaw and McKay (1942) documented for residential neighborhoods in central Chicago. However, in Bell's (1960) seminal formulation, organized crime offered a "queer ladder of social mobility" along which Irish, Jews and Italians had moved in sequence. Cloward and Ohlin (1960:199-202) and Glazer and Moynihan (1970:210-1) called attention to tensions between established Italian racketeers and black and Puerto Rican newcomers, exclaiming over the retarded pace of ethnic succession. More recently, Ianni (1974) has concluded that black and Spanish-speaking minorities are replacing Italians in some sectors of organized crime. "Ethnic groups move in and out of organized crime," writes Ianni (1974:14) "and their time in control comes and goes." Advancing the same idea, Albin (1971:153; but cf. 1974:119-20) also emphasized the spectrum of ethnic and racial minorities in America who have engaged in syndicated crime at one time or another. In all cases, the ethnic diversity of criminals indicated that syndicated crime was a structurally-engendered response to disadvantage rather than a cultural proclivity. Merton (1957:192-4) and Cloward and Ohlin (1960:150-3, 194-202) advanced the view that blockage of legitimate avenues of social mobility was the structural condition which engendered syndicated crime as one deviant response. Although Smith (1975) has cast the response to illegal enterprise in terms of labeling, the anomie theory is still the orthodox sociological explanation of why ethnic and racial minorities have always been disproportionately involved in illegal enterprise in America (Humphries, 1973). The anomie theory is more complex than

a simple demand theory because it identifies American cultural values (wealth) and blocked opportunities as prerequisites of illegal enterprise. Nonetheless, the anomie theory also concludes that, given these prerequisites, demand does beget supply. Demographic, cultural or social organizational characteristics of minorities play no role. The anomie theory thus rebuts and excludes the import theory, its ideological predecessor and rival.

Although the import and functionalist theories developed as ideological rivals, no necessary repugnance separates them. That is, the public's demand for illegal commodities does not preclude the possibility that cultural, organizational or demographic characteristics of ethnic groups might also affect the timing, duration, price or scale of the supply engendered. In fact, a close reading of leading criminologists reveals a largely implicit convergence around the view that illegal enterprise is neither an import nor a structural function but rather, a synthesis of ethnic characteristics and American society. For example, Cressey (1969) has been cited recurrently as the principal criminological exponent of the view that the *Cosa Nostra* is a confederation of Italian crime families whose origins derive from the Sicilian Mafia. Nonetheless, Cressey (1969:72) had no trouble acknowledging that the Italian crime confederation "thrives because a large minority of citizens demand the illicit goods and services it has for sale."

A critic of Cressey's (1969) interpretation of the history and formal organization of Italo-American crime syndicates in the United States, Ianni (1972) also has developed a position which implicitly reconciles the functionalist and transplantation ideas. Like others, Ianni (1972:61) concluded that organized crime "is that part of the business system operative in the illicit segment of American life." At the same time, Ianni's close observation of an Italo-American crime family led him to emphasize the importance of familism and clanship in its business operations. Rejecting Cressey's view of a bureaucratic conspiracy, Ianni (1972:155) nonetheless concluded that "the origins of this familism are Italian and not American." This con-

clusion swings Ianni into conformity with those who implicitly believe that crime syndicates in the United States are not simple products or "reflections of our national culture" but complex fusions of ethnic heritages and American society.

Why should this convergence be surprising? Insofar as illegal enterprise is really a mode of business enterprise, one expects parallels between legal and illegal enterprise. Recent studies of minority business enterprise in legal industries reveal that ethnic styles of economic organization affect the manner and extent to which minority businessmen respond to American consumers. Comparing Chinese, Japanese, native blacks and West Indian blacks, Light (1972) found that Asian and West Indian business enterprise benefited from forms of cooperation and finance derived from overseas cultural heritages. Lacking these modes of association, Southern-born blacks in the North were less active in business enterprise than other nonwhites, although their disadvantage in the general labor market was no less. Bonacich (1975) and Petersen (1972) also advance the conclusion that Japanese-American solidarity contributed to their success, especially their business success. Wong (1974) found that Chinese-American grocers in South-Central Los Angeles, a black ghetto, were more likely than black grocers in the same neighborhood to be members of a business or trade association and to employ family members in the firm. Loewen (1971) emphasized the cultural bases of Chinese business enterprise in Mississippi. Bonacich et al. (1976) probed the overrepresentation of Koreans in the business population of Los Angeles. Caudill and De Vos (1956), Hsu (1972) and Kitano (1969) also conclude that the cultural background of Asians in the United States encouraged group social mobility in general, and business enterprise in particular. Several overseas studies reach parallel conclusions. Marris and Somerset (1971) compared and contrasted the entrepreneurial styles of Africans and Hindus in Kenya, concluding that the East African family encouraged a more individualistic approach to business enterprise than the Hindu. Stokes (1974) ob-

served that white Afrikaners long eschewed business enterprise, but turned to it abruptly when business was ideologically defined as supportive of nationalistic goals.

Weber (1958) pointed out that the religious beliefs of the Protestant sectarians channeled energies of the faithful into business enterprise. Sombart (1951) claimed that exclusion of Jews from medieval trades encouraged them to turn their rationalist tradition into capitalistic endeavors. Schumpeter (1962) developed his theory of capitalism around the cultural bases of entrepreneurship in the bourgeois family. American literature (McClelland, 1967; McClelland and Winter, 1969; Miller and Swanson, 1958) has been psychological in outlook, quite overlooking structural pressures. Withal, their conclusions support the view that characteristics of groups sometimes endow them for particular modes of success.

Reviewing this vast literature, Smelser (1976:126) concluded that "the market for entrepreneurial services has a demand side and a supply side." The demand side consists of "market opportunities," but socio-cultural characteristics of subgroups govern the supply side. Indeed, the sociologists must insist upon the identity of subgroups or consider whether, as Moore (1974:ix) claims, illegal enterprise be an economic rather than a sociological phenomenon. As matters stand, the outstanding critics of the cultural-structural synthesis are, in fact, economists. Recent tendencies to press the analogies between illegal and legal enterprise (Lasswell and McKenna, 1972:108) encouraged economists to make contributions to this growing literature. Their extensive writings have proceeded on the basis of the usual postulates of utilitarian individualism, producing significant illumination of the differences between illegal enterprise and syndicated crime, business and extortion, and retail and wholesale levels of illegal enterprise (Becker, 1968; Schelling 1967; 1971; Rubin, 1973). This useful literature has developed on the explicit presumption that cultural heritage and ethnic social organization are extraneous to the conduct of illegal enter-

prise. Yet, Anderson's (1974) economic study of a Cosa Nostra family returns to the recognition that its style of operation reflected Italian cultural origins. Thus, even some economists agree that socio-cultural characteristics of subgroups affect the manner in which they conduct illegal enterprises.

Unfortunately, the predominance of Italo-Americans in syndicated crime today has encouraged confusion between the details of Italo-American syndicates and the general problem of illegal enterprise. To escape this confusion, Ianni (1974:15-6) has recommended the comparison of Italian and non-Italian crime. This comparison is "essential to isolate the basic structure of organized crime in American society." Ianni's (1974) comparative research on blacks and Cubans has begun this effort. Helmer (1975) recently has completed a historical comparison of narcotics laws in relation to blacks, Chinese and Mexicans in the United States.

This paper approaches illegal enterprise by means of a comparison between Chinese and blacks in the vice industry between 1880 and 1944. Prostitution was the largest illegal industry of the late nineteenth and early twentieth centuries (Bell, 1960:165). Indeed, until the Mann Act of 1910 put a stop to it, this business involved the international and interstate traffic in women. The contrast of blacks and Chinese in this industry is a contrast of cultural heritages in a similar social setting. Since both Chinese and blacks are visibly nonwhite, and were disadvantaged on that account, the Chinese-black comparison holds constant the otherwise distracting color difference between white and nonwhite. In addition, the black-Chinese comparison offers a sharp test of the fusion hypothesis because, unlike Southern blacks, Chinese immigrants left a society in which secret criminal organizations already existed. These organizations were lodges of the Triad Society (Schlegel, 1866; Blythe, 1969; Elegant, 1976). Therefore, the black-Chinese comparison involves one group which did not (blacks) and one which did (Chinese) have a foreign tradition of illegal enterprise from which to draw in response to the

reward system of American urban society. If ethnic heritage ever makes a difference, black-Chinese comparison ought to discover it, and provide leads to the nature of the difference.

THE ETHNIC VICE INDUSTRY, 1880-1920

Sutherland and Cressey (1970:260) attribute the turn-of-the-century prominence and subsequent decline of prostitution to the normalization of the sex ratio in the U.S. population, and the liberalization of sexual mores. The decrease in the proportion of the population single, and increase in the proportion married should be added (Table 1). Liberalization of sexual mores adversely affected prostitution because promiscuous sexual contacts reduced consumer demand. The incremental normalization of the sex ratio (Table 2) adversely affected prostitution because the surplus of able-bodied men first dwindled, then disappeared. The increasing percentage of married men adversely affected prostitution because the married have less opportunity or motive to frequent prostitutes than the single. As long as it existed, the cadre of supernumerary bachelors represented a sector of the U.S. population in which demand for commercial sex contacts was pronounced (Polsky, 1969:21). The predominance of youthful bachelors was largely a result of the sojourning new immigrants from Southern and Eastern Europe. Foreign white immigrants commonly expected to return to their homeland after a brief, lucrative sojourn in the United States. Indeed, in the period between 1890-1910, approximately

40 percent of foreign whites admitted actually did repatriate (Petersen, 1968:268; Axelrod, 1972:32-49). Those who came to sojourn left their families behind in Europe. When World War I and then the Immigration Act of 1924 curtailed new immigration from Europe, settlers replaced sojourners in the foreign white population and, with natural increase, their numbers of males and females tended toward parity (Table 2).

These changes in the sex ratio of the United States population had special implications for blacks and Chinese in industrial cities. Disadvantaged in the general labor force, blacks and Chinese had a motive to find compensatory livelihoods in illegal industries. In the period of severest imbalance in the American sex ratio, roughly 1880-1924, a large class of white men existed who wanted to purchase sexual contacts (Chicago Vice Commission, 1911:114-6, 228). This demand encouraged blacks and Chinese to enter the vice industry. A white-patronized, ethnic-staffed vice industry thus developed in both communities for the identical reason. Naturally, blacks and Chinese continued to conduct a vice traffic for co-ethnics throughout this period. However, white demand permitted many more blacks and Chinese to find employment in the vice industry than would have been possible on the basis of co-ethnic patronage alone. White patronage probably doubled the volume of prostitution in Chinatowns and tripled it in Harlem and Bronzeville. Even so, these ethnic industries never claimed more than perhaps a third of total white vice traffic in this period.
